Similarly, in Fig. 5(*g*),

$$H_2 = 1.311\, E\, \Delta_1 - 0.075\, E\, \Delta_2 \ldots\ldots\ldots\ldots\ldots (15b)$$

In Fig. 5(*h*),

$$H_3 = -\,0.193\, E\, \Delta_1 + 0.316\, E\, \Delta_2 \ldots\ldots\ldots\ldots\ldots (15c)$$

and, in Fig. 5(*i*),

$$H_4 = 0.032\, E\, \Delta_1 + 0.100\, E\, \Delta_2 \ldots\ldots\ldots\ldots\ldots (15d)$$

Substituting Eqs. 15 in Eqs. 14,

$$1.670\, E\, \Delta_1 + 0.194\, E\, \Delta_2 = 500 \ldots\ldots\ldots\ldots\ldots (16a)$$

and

$$0.198\, E\, \Delta_1 + 0.685\, E\, \Delta_2 = 500 \ldots\ldots\ldots\ldots\ldots (16b)$$

Solving Eqs. 16 simultaneously, $E\, \Delta_1 = 222$, and $E\, \Delta_2 = 666$.

Step 5. The numerical values of the moments caused by each deformation are determined by substituting the values of $E\,\Delta_1$ and $E\,\Delta_2$ in the moment terms shown in brackets in Figs. 5(*b*) and 5(*c*), and the following final moments in foot-pounds at the ends of all members are determined by summation: $M_{AB} = -2{,}838$; $M_{BA} = -2{,}345$; $M_{CD} = -1{,}612$; $M_{DC} = -799$; $M_{DE} = -1{,}407$; $M_{ED} = -1{,}954$; $M_{DF} = 2{,}203$; $M_{FG} = -1{,}109$; and $M_{GF} = -1{,}111$.

Example 5. Vierendeel Truss.—Fig. 6(*a*) represents a simple Vierendeel truss that supports a vertical load of 10 kips at the center of the chord BC. Values of E and I are assumed constant throughout.

Step 1. Three possible conditions of deformation exist—one for the transverse load on BC, and one for deformation of each panel of the structure. These are shown in Figs. 6(*b*), 6(*c*), and 6(*d*).

Step 2. Fixed-end moments are computed for the deformation conditions of Figs. 6(*b*), 6(*c*), and 6(*d*), and recorded as shown.

Step 3. The joints in Figs. 6(*b*), 6(*c*), and 6(*d*) are balanced and the final moments for each case are shown in brackets.

Step 4. To determine the values of $E\,R_1$ and $E\,R_2$, two equilibrium equations for the truss must be written. In Fig. 6(*e*), from $\Sigma F_y = 0$,

$$V_1 + V_2 = 7.5 \qquad (17a)$$

and, in Fig. 6(*f*), from $\Sigma F_y = 0$,

$$V_3 + V_4 = 2.5 \qquad (17b)$$

In Fig. 6(*g*), from $\Sigma M_c = 0$,

$$V_1 = \frac{55.38 + 6.23\,E\,R_1 - 1.82\,E\,R_2}{12} \qquad (18a)$$

In Fig. 6(*h*), from $\Sigma M = 0$,

$$V_2 = \frac{1.70 + 6.23\,E\,R_1 - 1.82\,E\,R_2}{12} \qquad (18b)$$

In Fig. 6(*i*), from $\Sigma M = 0$,

$$V_3 = \frac{-8.30 + 1.82\,E\,R_1 - 6.23\,E\,R_2}{12} \qquad (18c)$$

In Fig. 6(*j*), from $\Sigma M = 0$,

$$V_4 = \frac{1.24 + 1.82\,E\,R_1 - 6.23\,E\,R_2}{12} \qquad (18d)$$

Substituting Eqs. 18 in Eqs. 17,

$$12.46\,E\,R_1 - 3.65\,E\,R_2 = 32.92 \qquad (19a)$$

and

$$3.64\,E\,R_1 - 12.46\,E\,R_2 = 37.06 \qquad (19b)$$

Solving Eqs. 19 simultaneously, $E\,R_1 = 1.94$; and $E\,R_2 = -2.43$. (Note that these are relative R-values corresponding to $R = 0$ for the vertical members of the frame. The moments obtained using these R-values will be correct, however, as can readily be seen by reference to the general slope-deflection equation.)

FIG. 6.—VIERENDEEL TRUSS

Step 5. The summation of the moments in Figs. 6(*b*), 6(*c*), and 6(*d*) and the final values of the moments in foot-kips at the ends of all members are shown in Fig. 6(*k*).

NONRECTANGULAR FRAMES

Nonrectangular or quadrangular frames, such as trapezoidal bents, gable bents, and Vierendeel trusses with inclined upper chords, are frequently used in practice. Their behavior under the action of applied forces which cause linear displacements of the joints (deformations of the quadrangles) is radically different from that of rectangular frames under similar conditions, as will be noted in the problems of this section.

Relation Between Values of R for Members of a Quadrangle.—The quadrangle represented in Fig. 7 is deformed by external forces (not shown) so that joints B and C move to positions B′ and C′, respectively. The member AD is assumed to remain fixed in direction during the displacements of B and C. It is desired to find the relations between the values of R for AB, BC, and CD.

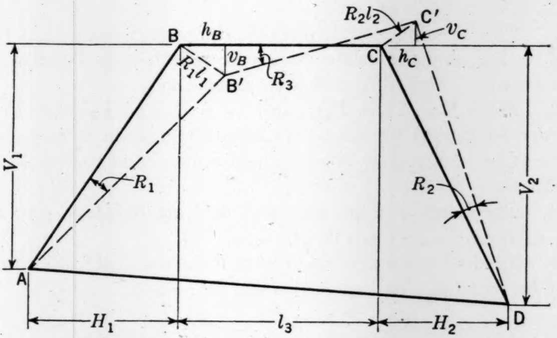

FIG. 7.—DEFORMATION OF A QUADRANGLE

Let l_1, l_2, and l_3 represent the lengths of members AB, CD, and BC, respectively, and R_1, R_2, and R_3 the corresponding values of R. Let H_1 and V_1 represent the horizontal and vertical projections of AB, and H_2 and V_2 the horizontal and vertical projections of CD. Let h_B and v_B represent the horizontal and vertical components of the displacement of B, and h_C and v_C the horizontal and vertical components of the displacement of C.

From similar triangles, the following relations may be written: $\frac{h_B}{R_1 l_1} = \frac{V_1}{l_1}$; and $\frac{v_B}{R_1 l_1} = \frac{H_1}{l_1}$. Therefore, $h_B = R_1 V_1$, and $v_B = R_1 H_1$. Similarly, it may be shown that $h_C = R_2 V_2$, and $v_C = R_2 H_2$. Since $h_B = h_C$, $R_1 V_1 = R_2 V_2$; and

$$R_2 = \frac{R_1 V_1}{V_2} \qquad (20a)$$

Also, since the vertical displacement of C relative to B equals $-(v_B + v_C) = -(R_1 H_1 + R_2 H_2)$,

$$R_3 = \frac{-(R_1 H_1 + R_2 H_2)}{l_3} \quad \text{(20b)}$$

Eqs. 20 are the desired relations which enable one to express R_2 and R_3 for members CD and BC, respectively, in terms of R_1 for AB.

In the quadrangles of many frames, the projections V_1 and V_2 of AB and CD, Fig. 7, will be equal. Eqs. 20 may then be written:

$$R_2 = R_1 \quad \text{(21a)}$$

and

$$R_3 = \frac{-R_1 (H_1 + H_2)}{l_3} \quad \text{(21b)}$$

Example 6. Trapezoidal Bent.—Fig. 8(*a*) represents a trapezoidal bent (9*a*) with a horizontal load of 200 lb applied at B and an unsymmetrical vertical load of 1,000 lb on BC.

Step 1. Two possible conditions of deformation exist—one for the transverse load on BC, and the other for lateral deflection (sidesway) of the frame. These are shown in Figs. 8(*b*) and 8(*c*), respectively.

Step 2. From Eqs. 21 in Fig. 8(*c*), $R_2 = R_1$ and $R_3 = -R_1$. Fixed-end moments are computed for this deformation condition in terms of $E R_1$, and for the condition of Fig. 8(*b*) in numerical values, and recorded on the appropriate sketches.

Step 3. The joints in Figs. 8(*b*) and 8(*c*) are balanced and the final moments for each case are shown in brackets.

Step 4. To determine the value of $E R_1$, an equilibrium equation for the bent must be written. In Fig. 8(*d*), from $\Sigma F_x = 0$,

$$H_1 + H_2 = 200 \quad \text{(22)}$$

In Fig. 8(*e*), from $\Sigma M_C = 0$,

$$V_1 = 221.4 - 1.384\, E R_1 \quad \text{(23a)}$$

and, from $\Sigma M_B = 0$,

$$V_2 = 778.6 + 1.384\, E R_1 \quad \text{(23b)}$$

The values of V_1 and V_2 in Eqs. 23 are shown acting in Figs. 8(*f*) and (8*g*), respectively. In Fig. 8(*f*), from $\Sigma M = 0$,

$$H_1 = \frac{20.30\, E R_1 - 1{,}692}{15} \quad \text{(24a)}$$

and, in Fig. 8(*g*), from $\Sigma M = 0$,

$$H_2 = \frac{20.30\, E R_1 + 4{,}908}{15} \quad \text{(24b)}$$

Substituting Eqs. 24 in Eq. 22,

$$\frac{20.30\, E R_1 - 1{,}692}{15} + \frac{20.30\, E R_1 + 4{,}908}{15} = 200 \quad \text{(25)}$$

and solving Eq. 25, $E R_1 = -5.32$.

Step 5. Summation of the moments in Figs. 8(*b*) and 8(*c*) gives the following final moments: $M_{AB} = 228$; $M_{BA} = 428$; $M_{BC} = -428$; $M_{CB} = 640$; $M_{CD} = -640$; and $M_{DC} = -304$.

Example 7. Two-Story Bent with Horizontal Loads.—Fig. 9(*a*) represents a two-story bent with inclined legs which carries horizontal loads applied at joints B and E.

FIG. 8.—TRAPEZOIDAL BENT

Step 1. Two possible conditions of deformation exist—one for primary deformation of the first story which in turn causes secondary deformation of the second story, and the other for the deformation of the second story of the frame. These are shown in Figs. 9(*b*) and 9(*c*).

Step 2. By use of Eqs. 21, the *R*-values for all members in Fig. 9(*b*) have been expressed in terms of R_1 for AB, and for all members in Fig. 9(*c*) in terms of R_2 for BE. The corresponding fixed-end moments, in terms of $E\,R_1$ and $E\,R_2$, are recorded on these sketches.

FIG. 9.—TWO-STORY BENT WITH HORIZONTAL LOADS

Step 3. The joints in Figs. 9(*b*) and 9(*c*) are balanced and the final moments for each case are shown in brackets.

Step 4. To determine the values of $E\,R_1$ and $E\,R_2$, two equilibrium equations for the bent must be written. In Fig. 9(*d*), from $\Sigma F_x = 0$,

$$H_1 + H_2 = 200 \qquad (26a)$$

and, in Fig. 9(*e*), from $\Sigma F_x = 0$,

$$H_3 + H_4 = 100 \qquad (26b)$$

In Fig. 9(*d*), from $\Sigma M_D = 0$,

$$V_1 = \frac{-\,11.28\,E\,R_1 + 1.56\,E\,R_2 + 4{,}500}{15} \qquad (27a)$$

and, in Fig. 9(*e*), from $\Sigma M_C = 0$,

$$V_2 = \frac{-\,1.48\,E\,R_1 - 10.04\,E\,R_2 + 1{,}500}{10} \qquad (27b)$$

The values of V_1 and V_2 in Eqs. 27 are shown acting in Figs. 9(*f*), 9(*g*), 9(*h*), and 9(*i*). In Figs. 9(*f*) and 9(*g*), respectively, from $\Sigma M = 0$,

$$H_1 = H_2 = \frac{54.54\,E\,R_1 - 12.42\,E\,R_2 + 4{,}500}{90} \qquad (28a)$$

In Figs. 9(*h*) and 9(*i*), respectively, from $\Sigma M = 0$,

$$H_3 = H_4 = \frac{11.64\,E\,R_1 + 35.56\,E\,R_2 + 1{,}500}{60} \qquad (28b)$$

Substituting Eqs. 28 in Eqs. 26,

$$\left.\begin{array}{l} 54.54\,E\,R_1 - 12.42\,E\,R_2 = 4{,}500 \\ 11.64\,E\,R_1 + 35.56\,E\,R_2 = 1{,}500 \end{array}\right\} \qquad (29)$$

Solving Eqs. 29 simultaneously, $E\,R_1 = 85.7$ and $E\,R_2 = 14.1$.

Step 5. The numerical values of the moments in Figs. 9(*b*) and 9(*c*) may now be calculated, and the following moments at the ends of all members are determined by summation: $M_{AB} = M_{DC} = -\,472$; $M_{BA} = M_{CD} = -\,434$; $M_{BE} = M_{CF} = -\,134$; $M_{EB} = M_{FC} = -\,308$; $M_{BC} = M_{CB} = 569$; and $M_{EF} = M_{FE} = 308$.

Example 8. Gable Bent.—Fig. 10(*a*) represents a gable bent with a horizontal load of 1,000 lb applied at joint B.

Step 1. Two possible conditions of deformation exist—one for deformation of EDCB; and the other for linear displacement of B which in turn causes an equal displacement of D (an alternate deformation of ABCD might be used instead). These are shown in Figs. 10(*b*) and 10(*c*), respectively.

Step 2. By use of Eqs. 20, the *R*-values for all members in Fig. 10(*b*) have been expressed in terms of R_1 for ED, and the *R*-value of ED in Fig. 10(*c*) has been expressed in terms of R_2 for AB. The corresponding fixed-end moments, in terms of $E\,R_1$ and $E\,R_2$, are recorded on these sketches.

Step 3. The joints in Figs. 10(*b*) and 10(*c*) are balanced and the final moments for each case are shown in brackets.

Step 4. To determine the values of $E\,R_1$ and $E\,R_2$, two equilibrium equations for the bent must be written.

In Fig. 10(*d*), from $\Sigma F_x = 0$,

$$H_1 + H_3 = 1{,}000 \qquad (30a)$$

FIG. 10.—GABLE BENT

and, in Fig. 10(*e*), from $\Sigma F_x = 0$,

$$H_1 - H_2 = 0 \qquad (30b)$$

In Fig. 10(*f*), from $\Sigma M = 0$,

$$H_1 = -\,2.402\,E\,R_1 - 3.122\,E\,R_2 \qquad (31a)$$

in Fig. 10(*g*), from $\Sigma M = 0$,

$$H_3 = 0.198\,E\,R_1 - 0.767\,E\,R_2 \qquad (31b)$$

and, in Fig. 10(*h*), from $\Sigma M_B = 0$,

$$V = 0.236\,E\,R_1 + 0.448\,E\,R_2 \qquad (31c)$$

The value of V in Eq. 31*c* is shown acting in Fig. 10(*i*) in which, from $\Sigma M_B = 0$,

$$H_2 = 0.802\,E\,R_1 + 0.400\,E\,R_2 \qquad (31d)$$

Substituting Eqs. 31 in Eqs. 30

$$\left.\begin{aligned} -2.204\,E\,R_1 - 3.889\,E\,R_2 &= 1{,}000 \\ -3.204\,E\,R_1 - 3.522\,E\,R_2 &= 0 \end{aligned}\right\} \ldots\ldots\ldots\ldots\ldots (32)$$

Solving Eqs. 32 simultaneously, $E\,R_1 = 748$; and $E\,R_2 = -680$.

Step 5. The numerical values of the moments in Figs. 10(*b*) and 10(*c*) may now be computed, and the final moments at the ends of all members are determined by summation: $M_{AB} = 6{,}970$; $M_{BA} = 3{,}740$; $M_{BC} = -3{,}740$; $M_{CB} = -2{,}250$; $M_{CD} = 2{,}250$; $M_{DC} = 550$; $M_{DE} = -550$; and $M_{ED} = 3{,}800$.

CONCLUSIONS

In this paper a method of procedure has been developed whereby the principle of superposition is utilized in conjunction with the slope-deflection or moment distribution method in the analysis of rigid frames.

The following conclusions are based on the foregoing analyses:

1. The method of procedure is general, and the results obtained are exact for the assumptions commonly made in rigid frame analysis.
2. Although many computations are required in the analysis of a frame having a large number of deformation conditions, the calculations are simple and all operations of multiplication and division may usually be performed with sufficient accuracy on a 10-in. slide rule.
3. At all times special care must be given to the correct formulation of equilibrium equations and, in the case of nonrectangular frames, to the determination of the relative R-values for the members of the quadrangles of the frame being considered.
4. For frames of unusual proportions where convergence by the moment distribution method is slow, it is recommended that the slope-deflection method be used to balance the moments at the joints in step 3 of the outline of method of procedure.
5. The principle of superposition is an indispensable aid in the analysis of rigid frames of all types in which applied loads cause linear displacements of the joints.

DISCUSSION

F. S. Merritt,[4] **Jun. Am. Soc. C. E.**—Although no new method of analysis is proposed (see "Synopsis"), this paper is of value in illustrating the application of the principle of superposition to different types of frames. As Professor Wilson acknowledges, the principle of superposition is usually stated in textbooks on structural analysis; but, contrary to his opinion, it is also strongly emphasized in texts discussing moment distribution, since it is the most convenient tool for analyzing rigid frames by this method. However, nowhere in this paper is the principle of superposition, the subject of the paper, clearly stated or defined; nor are the limits of its validity described.

In the outline of the method of procedure, five steps are given for the solution of any rigid frame problem. Hardy Cross and N. D. Morgan, Members, Am. Soc. C. E., describe this same procedure simply and succintly as follows (*3a*):

> "In analyzing a bent by moment distribution we first assume no movement of the joints and analyze for this condition, find by statics the force necessary to prevent such movements and find the moments which it would produce, and then take the difference of the two results."

The writer has developed the following procedure (16):

> "1. Apply forces to the structure to prevent sidesway while the fixed-end moments due to loads are distributed.
> "2. Compute the moments due to these forces.
> "3. Combine the moments obtained in Steps 1 and 2 to eliminate the effect of the forces."

When moment distribution by the method of moment ratios (16) is used, there is never any need to revert to the slope-deflection method, because the question of convergence does not arise. The author's recommendation in conclusion 4, therefore, is not generally valid.

In applying either of these last two procedures, sketches may be desirable, but they are not necessary. From a practical viewpoint, the preparation of sketches requires time, and, where the calculations can follow a rigid procedure in which mistakes can be avoided without the use of sketches, such a procedure is recommended. In the classroom, sketches are useful in the introduction of an unfamiliar subject, but, in a drafting room, where time is money and a designer is assumed to be familiar with structural analysis, time-saving procedures should be adopted. Consequently, step 1 of the paper should be optional with the designer and should be included as a suggestion to facilitate determination of signs rather than as a step in the procedure.

In analyzing rigid frames, a designer generally wishes to obtain separately the effects of dead load, live load, wind, etc. The determination of live load moments might require the plotting of influence lines. In reality, this is the rigid frame problem, as contrasted to the classroom problem of a given structure with a fixed loading condition. Professor Wilson does not state how his procedure could be used under changing load conditions without the necessity of going through all five steps for each change in position or magnitude of loads. As a matter of fact, the writer has used the three steps outlined herein as the base of a simple procedure in which the principle of superposition is utilized to obtain the separate effects of varied loading conditions without the necessity of distributing fixed-end moments for every condition (16). The practice of computing and placing final moments on sketches, as recommended in steps 2 and 3 by the author, is cumbersome in view of the great number of sketches required and the difficulty in making summations and combinations from them.

---

[4] Field Service Engr., D. W. Haering & Co., New York, N. Y.

The writer agrees with all the conclusions of the paper except conclusion 4.

Ralph W. Stewart,[5] M. Am. Soc. C. E.—In his opening sentence Professor Wilson states that the purpose of his paper "is to demonstrate the usefulness of the principle of superposition in the analysis of rigid frames by the slope-deflection and moment distribution methods." From an examination of the demonstrations the writer concludes that, for multistory frames with sloping columns and for the Vierendeel truss, the author has accomplished his purpose.

However, in his treatment of one-story and two-story frames with vertical columns, Professor Wilson introduces undesirable complexities and also so much unnecessary arithmetic that the writer does not consider this part of the paper useful. To uphold this conclusion the writer presents Fig. 11, which is the bent shown in Fig. 1, using the moment values in Eqs. 4. By equating the sums of the moments about joints B and C, respectively, to zero and then consolidating terms the author obtains Eqs. 5, containing three unknown quantities. To solve them he introduces Eqs. 7 and 8 from which $E\,R$ may be evaluated; and then Eqs. 5 can be solved for θ_B and θ_C.

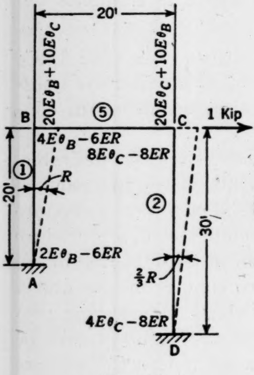

Fig. 11

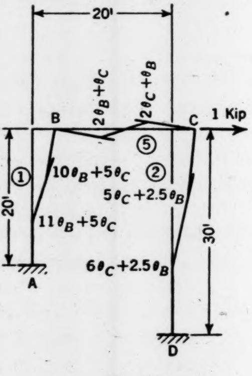

Fig. 12

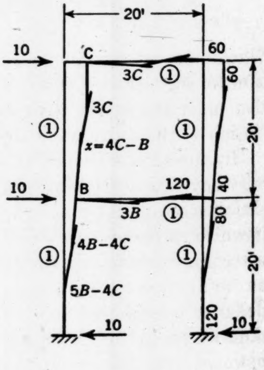

Fig. 13

---

[5] Bridge Engr., City of Los Angeles, Los Angeles, Calif.

Fig. 12 is a graph of the traverse of the elastic curves of Fig. 11. In Fig. 12 the geometrical values of the angles of flexure in terms of θ_B and θ_C are shown. For the beam each angle value is the same as the parenthetical term in a slope-deflection equation for this member. The properties of these angles have been published (17). They are located at the one-third points of the members.

Since the left column is only one fifth as stiff as the beam, its angle of flexure for the moment at B will be five times as great as the flexure angle in the beam, or $10\,\theta_B + 5\,\theta_C$. To obtain the flexure angle for M_A it is only necessary (from the geometry of the figure) to add θ_B to the flexure angle for the moment at B, giving $11\,\theta_B + 5\,\theta_C$. A similar procedure gives the flexure angles for the right column. The unknown R does not appear in these angle values. A property of an elastic curve traverse is that a flexure angle multiplied by the member stiffness equals the moment that the angle measures. By multiplying the flexure angles by the K-values a set of relative moment values for Fig. 12 is obtained. The geometry of the flexure of the columns gives the deflections at points B and C. Writing the equilibrium equation, in which the sum of the column shears equals 1 kip, and the geometrical equation, which expresses the fact that the deflections at B and C are equal, and consolidating terms:

$$1.383\,\theta_B + 1.233\,\theta_C = 1 \quad\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (33a)$$

and

$$5.5\,\theta_B = 3.667\,\theta_C \quad\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (33b)$$

These equations, with only two unknown quantities, replace Eqs. 5 with three unknown quantities.

Solving, $\theta_B = 0.3093$ and $\theta_C = 0.464$. The flexure angles can now be evaluated. Multiplying these angles by the K-values of the members gives a set of moments which check Professor Wilson's moments to slide-rule accuracy.

To solve the two-story symmetrical frame illustrated by Fig. 4, the author's procedure involved the following work: Steps 1 and 2, two end-moment distribution procedures for the frame; and, step 3, the development and solution of two simultaneous formulas (Eqs. 13). The two end-moment distribution operations were unnecessary as all of the work accomplished by these three stages of the author's solution can be accomplished by two simultaneous equations taken from the traverse diagram in Fig. 13.

To reduce the labor of typing and engraving, B and C have been substituted for θ_B and θ_C in Fig. 13 and the equations relating to this frame. The beam flexure angles $3\,B$ and $3\,C$ are shown in Fig. 13. Since the members are of equal stiffness, the uppermost column flexure angle is also $3\,C$. By angle summation for the upper column: $C + 3\,C - x - B = 0$, or $x = 4\,C - B$, as shown. Balancing moments about point B gives $4\,B - 4\,C$ as the upper flexure angle for the lower column. By angle summation $B + 4\,B - 4\,C$, or $5\,B - 4\,C$, is the bottom flexure angle as shown. Top-story shear balance gives: $7\,C - B = 100$; bottom-story shear balance gives: $9\,B - 8\,C = 200$; and solving: $B = 40$ and $C = 20$. The moments (which are the same as those in the paper) appear in the right half of Fig. 13. The labor involved in this solution is much less than that required by the author's multistage demonstration.

Even if the principle of superposition were mandatory for all the demonstration problems, Professor Wilson has, in general, performed more than double the necessary preliminary work by restricting his paper to slope deflection and end-moment distribution. For example, the work in Fig. 5(*a*) involved one hundred and twenty-eight arithmetical operations. With the traverse method, the results can be duplicated with thirty-seven arithmetical operations and two slide-rule settings from one of which seven readings are taken; and from the other setting, four readings.

The traverse solution also has some automatic checks which end-moment distribution does not. For example, in Fig. 5(*a*), M_{CE} should be exactly six times M_{EC}. The author's solution yields $6 \times 208 = 1{,}268$. The correct value of M_{EC} is 211.3. This difference in moments is not important but the fact that the traverse method offers checks not offered by end-moment distribution is important. Also the author's solution is applicable to only one position of the live load whereas the traverse solution can be used for any position of the live load.

For Fig. 4(*c*) all the arithmetical work needed to compute the moments by the traverse method is as follows: $2 + 3 = 5$; $4\,x = 6$; $x = 1\tfrac{1}{2}$; $3\,x = 4.5$; $3 + 10 - 4.5 = 8.5$; and $6 \times 1 = 6$. Finally:

$$\begin{array}{ccc} & \text{Traverse results} & \text{Wilson results} \\ \dfrac{6\,E\,R}{8.5} \times & \left\{\begin{array}{l} 4.5 = 3.176\,E\,R \\ 5.0 = 3.529\,E\,R \\ 3.0 = 2.121\,E\,R \\ 2 = 1.412\,E\,R \\ 1 = 0.706\,E\,R \end{array}\right. & \begin{array}{l} 3.17\,E\,R \\ 3.54\,E\,R \\ 2.12\,E\,R \\ 1.42\,E\,R \\ 0.72\,E\,R \end{array} \end{array}$$

The detail of Professor Wilson's end-moment distribution is not given, but it must certainly have involved several times as much work as the foregoing. The traverse solution of Fig. 4(*b*) is equally simple.

To summarize: The paper is of value to engineers who design framed structures. Its usefulness is considerably impaired, however, by unnecessarily complex solutions for some of the problems due to the exclusion of the elastic curve traverse from the scope of the work.

JOHN E. GOLDBERG,[6] ASSOC. M. AM. SOC. C. E.—A commendable résumé of the application of the principle of superposition to the analysis of certain types of rigid frame structures is presented by Professor Wilson. The paper is an excellent coordination of this principle with the particular types of structures described.

The method of superposition will give a reasonable analysis in many cases where the solution by more direct methods may be comparatively tedious. This is true because in direct methods of analysis a large number of simultaneous equations must be solved, whereas in the method of superposition a limited number of modes of deformation are first analyzed and subsequently used as parameters in the solution of the complete framework. Obviously, using the latter procedure there are a smaller number of equations to solve simultaneously. The method of superposition is particularly applicable to frames of what may be termed intermediate complexity.

---

[6] Structures Engr., Consolidated Vultee Aircraft Corp., San Diego, Calif.

The writer has used similar methods for a number of years in conjunction with slope deflection and moment distribution for the analysis of several classes of structures—particularly Vierendeel trusses with cambered chords, A-frames, and simple or gabled bents—and also for the analysis of sidesway effects induced by unsymmetrical vertical loading or by transverse loading of building frames not more than a few stories in height. In such problems the method of superposition provides a simple and practicable method of analysis, particularly when used in conjunction with moment distribution or slope deflection (18)(19) and successive approximations or successive corrections. Certain of these problems have been analyzed by various writers in a number of texts and papers. The gabled bent, for example, has been "popular" in technical publications. The analysis of simple bents and bents with inclined legs likewise has been presented in several texts.

Some problems discussed by Professor Wilson may be solved at least as easily by direct methods without recourse to the method of superposition. Certain simple bents are generally in this class. A structure that may be analyzed easily by more direct methods is the Vierendeel truss with equal parallel chords or the structurally similar two-column bent with parallel equal columns. The attention of the writer was directed to this problem a number of years ago by the comparative impracticability of applying the usual popular methods to such structures when the outside members (that is, chords in the Vierendeel trusses or columns in the bents) are relatively stiff, say, five or more times as stiff as the interior members. In such cases moment or shear distribution is extremely slow in converging to the exact solution.

For a simple and practicable solution of this problem the writer derived the following exact formula from the basic slope-deflection equations:

$$\theta_n = \frac{1}{6\,K_{G_n} + K_{C_n} + K_{C_o}} \left(\frac{M_n + M_o}{2} + K_{C_n}\,\theta_m + K_{C_o}\,\theta_o \right) \ldots . (34)$$

in which K_{G_n} and K_{C_n} are the relative stiffnesses of the web members and of the chord members, respectively; and M_n is the product of the transverse external shear acting on the *n*th panel times the longitudinal dimension of the panel—that is, the distance between interior members. When the known K and M values are substituted, Eq. 34 reduces to an expression of the simple form,

$$\theta_n = A\,\theta_m + B\,\theta_o + C \ldots\ldots\ldots\ldots\ldots\ldots\ldots (35)$$

A similar equation is set up for each panel point along either chord. The series of equations thus obtained converge very rapidly. For example, in cases where the chords are from eight to ten times as stiff as the interior members, three or four cycles of these extremely simple calculations will give an accuracy better than twenty cycles (approximately) by the usual moment distribution or shear distribution procedure. The web-member end moments are given by the formula,

$$M_{Gn} = -3\,(K_{Gn}\,\theta_n) \ldots\ldots\ldots\ldots\ldots\ldots (36a)$$

and the chord-member end moments by the formula,

$$M_{Cnm} = \frac{M_n}{4} + \left(\frac{\theta_m - \theta_n}{2}\right) K_{Cn} \ldots\ldots\ldots\ldots\ldots (36b)$$

Obviously, a number of problems not treated by Professor Wilson may also be analyzed by the method of superposition. The method of superposition is an extremely general and practicable method, and Professor Wilson is to be commended for his clear and concise outline.

A. W. FISCHER,[7] ESQ.—The analysis of rigid frames by superposition as presented by the author is certainly another valuable method for the analysis of rigid frames. The illustrative examples presented in the paper show that the method is general and can be used for complex frames. In 1938 (20) the writer found the method of superposition very practicable for calculating moments in structures several bays wide and several stories high.

FIG. 14.—UNSYMMETRICAL THREE-COLUMN BENT

Example 2. Unsymmetrical Three-Column Bent.—The method of moment distribution as presented by Professor Wilson is general. In some cases considerable time can be saved by taking advantage of permissible short cuts. For example, the moment distribution in Fig. 3(*b*) can be shortened considerably by first balancing a joint and then carrying over one half of the balancing moment to the adjacent joints, before the adjacent joints are balanced. This method is correct theoretically, and the writer uses it in all his moment distribution analyses. Fig. 14 shows this method of balancing moments beginning at joint B. After carrying over one half of the balancing moment to the adjacent joints, the next step is to balance joint E. Finally, carry over one half of the balancing moment to joints adjacent to joint E and then balance joint C.

FIG. 15.—TWO-STORY BENT WITH HORIZONTAL LOADS

On comparison with the formal procedure of the paper the amount of labor is found to be reduced considerably.

Example 7. Two-Story Bent with Horizontal Loads.—For a symmetrical structure, such as Fig. 9, the *K*-factors for the horizontal members can be modified slightly by assuming that there is a point of inflection, or hinge, at the center, which makes the *K*-factor equal to $\frac{I}{0.5\,L} \times \frac{3}{4} = 1.5\,\frac{I}{L}$. Thus, the *K*-factors for members BC and EF are equal to $1.5 \times 1.5 = 2.25$, and no balancing moment need be carried over to the adjacent joints for these members. Fig. 15(*a*) gives the moment distribution for the final moments shown in

Fig. 9(*b*), and Fig. 15(*b*) shows the moment distribution for the final moments shown in Fig. 9(*c*). With this slight modification, considerable labor can be saved and the method is theoretically correct.

Example 6. Trapezoidal Bent.—Fig. 16(*a*) represents a single-story trapezoidal bent similar to Fig. 8, but with a bottom member and a horizontal load of 1,000 lb applied at joint A (compare analysis of this bent by A. Amirikian, M. Am. Soc. C. E. (1*a*)). For this example, $E = 1$, $R_2 = R_1$, and $R_3 = -R_1$. Since K for member AD is equal to 2 (Fig. 16), the fixed-end moment $M_{AD} = M_{DA} = -2 \times 6\,R_1 = -12\,R_1$. The fixed-end moment $M_{AB} = M_{BA} = 2 \times 6\,R_1 = 12\,R_1$. The fixed-end moment $M_{BC} = M_{CB} = -3 \times 6\,R_1 = -18\,R_1$ (Fig. 16(*b*)). The first joint balanced is joint C and one half of the balanced moments are carried to the adjacent joints. Next balance joint D and carry one half of the balanced moments to its adjacent joints, balance joint B and carry one half of the balanced moments to its adjacent joints, and balance joint A, carrying one half of the balanced moments to its adjacent joints. Repeat the process in the order of joints C, D, B, and A. The final moments are shown in brackets in Fig. 16(*b*), thus accounting for steps 1, 2, and 3.

By step 4 in the author's procedure (see Fig. 16(*c*)):

$$H_1 + H_2 = 1{,}000 \quad \text{(37)}$$

also, in Fig. 16(*d*),

$$V_1 = 4.085\,R_1 \quad \text{(38a)}$$

and

$$V_2 = 4.085\,R_1 \quad \text{(38b)}$$

The values of V_1 and V_2 in Eqs. 38 are shown in Figs. 16(*e*) and 16(*f*), respectively. In Fig. 16(*e*),

$$H_1 = \frac{29.51\,R_1}{12} \quad \text{(39a)}$$

and, in Fig. 16(*f*),

$$H_2 = \frac{40.11\,R_1}{12} \quad \text{(39b)}$$

Substituting Eqs. 39 in Eq. 37 and solving, $R_1 = \dfrac{12{,}000}{69.62}$.

In step 5, substituting the value of R_1 from step 4 in Fig. 16(*b*) gives the following final moments in foot-pounds: $M_{AB} = 2{,}006 = -M_{AD}$; $M_{BA} = 2{,}218 = -M_{BC}$; $M_{DA} = -1{,}672 = -M_{DC}$; and $M_{CB} = -1{,}879 = -M_{CD}$.

Example 5A. Vierendeel Truss with Inclined Chords.—This problem, of course, differs somewhat from Example 5 of the paper (compare analysis by Mr. Amirikian (1*b*)). Fig. 17(*a*) represents a five-bay Vierendeel truss with a 200-lb load at each lower panel point. The value of E is considered as unity throughout, and the values of $I/L = K$ are as shown. Figs. 17(*b*) and 17(*c*) show the left portion of the truss in the distorted condition with the R-values expressed in terms of R_1 and R_2 using Eq. 21. For this particular symmetrical truss assume a hinge in the center of the members AA′, BB′, and CC′ and multiply each K-value by 1.5 so that, with this slight modification, no balancing moment is required to be carried over to the adjacent joint for these members.

The fixed-end moments $6\ K\ R_1$ for the various members are shown in Fig. 18(*a*). For the moment distribution method the sequence is: Joints A, C, and B. For member CD the carry-over balanced moment from joint D to joint C is one half of the balance moment at joint C with the sign changed, because then it is necessary only to apply the moment distribution method to

FIG. 18.—MOMENT DISTRIBUTION, VIERENDEEL TRUSS

and

$$H_3 = \frac{2.98\,R_1 + 18.49\,R_2}{12} \qquad \text{(42d)}$$

Substituting Eqs. 42 in Eqs. 40,

$$100.08\,R_1 - 46.90\,R_2 = 4{,}800 \qquad \text{(43a)}$$

and

$$13.46\,R_1 + 58.24\,R_2 = 4{,}800 \qquad \text{(43b)}$$

Solving Eqs. 43 by determinants, $R_1 = 78.12$ and $R_2 = 64.36$.

The numerical values of the moments in Figs. 18(*a*) and 18(*b*) may now be calculated (step 5), and the following moments in foot-pounds at the ends of all members are determined by summation: $M_{AB} = M_{A'B'} = -977$; $M_{BA} = M_{B'A'} = -446$; $M_{BC} = M_{B'C'} = -207$; $M_{CB} = M_{C'B'} = -342$; $M_{CD} = M_{C'D'} = 136$.

The foregoing is intended to lend emphasis to the writer's sincere opinion that the method of superposition as presented by Professor Wilson is an unusually valuable tool for the solution of rigid frames.

LEON BLOG,[8] ESQ.—The importance of using the method of superposition when analyzing rigid frames is emphasized in this paper; but the paper has additional value. In the several examples, the author has explained various simplifications and clarifications previously unknown to the writer. Although superposition was not required for solving Example 1, there is considerable merit in the technique of its solution. By separating the *R*-term in Eqs. 1 and by writing it separately as in Eqs. 2, and then by expressing the *R*-term of other members in terms of that of one member, a considerable simplification in the statement of the values for the end moments occurs. Through stating the values of the angles of twist, θ, in terms of $E\,R$ as in Eqs. 6, it becomes unnecessary to evaluate θ and R quantitatively. Values of θ and R in radians are generally of a low order and lead to errors in the final moment values unless carried throughout the solution with many significant figures. Another simplification is that the value E occurs in both sides of Eqs. 6, so that, by the author's method, it need not be considered separately. Only the product $E\,R$ must be evaluated and substituted in the values of the end moments which are expressed solely in terms of $E\,R$. Use of the value of $E\,R$ leads to a minimum of error in the moment values sought. The technique just described is better than any known to the writer for the solution of rigid frames by either the slope deflection or the moment distribution methods.

Superposition is a method of solving, by steps, certain problems to which it is applicable. When solving problems dealing with rigid frames involving asymmetry of any kind, one-step solutions by moment distribution are not possible. Two steps are required: (*a*) Moment distribution to evaluate moments due to pure rotation of the joints; and (*b*) moment distribution to obtain moments due to movements occurring transversely to the axis of each member that can be deflected. The moments evaluated in each step are added algebraically at each joint to derive the required moment. Step 1 may be solved by any good system of moment distribution. Step 2 is often solved by the unbalanced shear method (2). Hardy Cross, M. Am. Soc. C. E., does not call step 2 anything, but unbalanced shears are actually the tools required when correcting for sidesway by his method.

---

[8] Structural Engr., City of Los Angeles, Los Angeles, Calif.

Professor Wilson does not use the unbalanced shear method in step 2. In solving Example 2, Fig. 3(*b*), he distributes fixed-end moments which are expressed in terms of $E\,R$. Then he evaluates $E\,R$ and uses it to evaluate the distributed moments. The moments thus found are added algebraically to those in Fig. 3(*a*) to get the working moments. This consummates a very direct solution of Example 2.

Example 3 is an extension of the technique exhibited by Example 2. In analyzing two stories, it is necessary to use a set of R-values: R_1 appertains to the lower story and R_2 to the upper tier. After that variation from Example 2, the technique of solution parallels that for Example 2.

For the solution of Example 4, the author evaluates moments in terms of $E\,\Delta$. Here, inspection will not yield R-values for the vertical members in terms of the R-value of a selected vertical member as illustrated in Example 1. In this example it was evident that the R-values for vertical members joined by the same horizontal member are inversely proportional to the length of the vertical members. In Fig. 5(*a*), the joint at D between points C and E precludes evaluation of deflection angles by inspection. Otherwise the method of solution closely follows that for Examples 2 and 3.

For solving the Vierendeel truss of Example 5, Professor Wilson is able to profit by expressing moments in terms of $E\,R$. Otherwise, the solution is self-explanatory.

Equally valuable is the exposition of the relation between the values of R for the members of a quadrangle. The knowledge of this relation permits a very direct attack upon the type of problem considered in the ensuing comment. The meaning of R_3 in Fig. 7 may be made somewhat clearer by drawing a horizontal line through B' toward the right to meet a perpendicular drawn downward from C'. Then

$$R_3 = \frac{v_C + v_B}{l_3} \qquad (44)$$

For the solution of the frame of Example 6, the R-relation in Eqs. 20 and 21 was used. Fig. 8 is not a quadrangle, but the fixity of the legs AB and CD is analogous to having a member such as AD of Fig. 7. Therefore, Eqs. 20 and 21 are applicable to the solution of Example 6. The distributed moments are determined by using $E\,R_1$ in a manner closely resembling the solution of Example 2.

Example 7, Fig. 9, is solved easily by using the quadrangle concept. The lower story has legs which are fixed, and so a fictitious member AD may be assumed. The second story is a full quadrangle. Otherwise the solution closely follows that of Example 3.

In Fig. 10(*b*) of Example 8, the author uses the quadrangle. The dashed line EB corresponds to AD of the basic quadrangle. Moments are all expressed in terms of $E R_1$ and $E R_2$, and thereafter the equations of statics dominate the solution.

Finally, the writer believes that Professor Wilson has made a distinct contribution to the analysis of rigid frames of homogeneous material. Should any of the members be variable in shape, the resultant variation of end moment of inertias would preclude the simplification which results in Eqs. 4 by using the concept of relative *K*-values. However, each Eq. 4 would merely contain the *K*-value for that member and would lead to some additional numerical work. If the frame is not homogeneous as to material, modular ratios such as those for reinforced concrete may be used to establish all the equations in terms of the *E* of a selected member. This also would involve some extra numerical work, but the extra work would be common to other known methods.

Arthur B. McGee,[9] Esq.—The principle of superposition is of great value for the analysis of rigid frames. The examples in the paper illustrate the method of procedure in a workable manner; but, since Examples 1, 2, 3, 4, 6, and 8 can be solved by shorter and easier methods, they do not demonstrate the value of the method. To do the method justice and to show its great value in solving difficult problems the writer wishes to show its application to a two-bay, saw-toothed structure with tapering members.

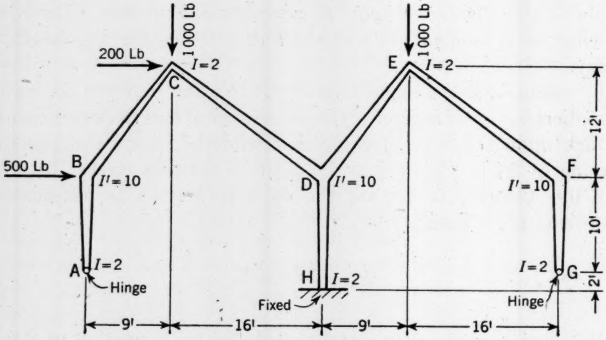

Fig. 19.—Two-Bay, Saw-Toothed Structure with Tapering Members

Fig. 19 shows such a frame loaded unsymmetrically with vertical and horizontal loads. The tapering members have been given the same moments of inertia at the ends so that one set of beam constants will suffice for all members. These constants are taken from the tables compiled by Walter Ruppel, Assoc. M. Am. Soc. C. E. (21). The application of these constants to the several members is given in Fig. 20 (17).

---

[9] Structural Design Engr., Bureau of Eng., City of Los Angeles, Los Angeles, Calif.

The notation used in this discussion varies slightly from the author's but should cause no confusion. The symbol d is used herein for the linear displacement of one end of a member, and Δ represents an angle equal to an $\frac{M}{E\,I}$-area. Also the writer considers an end moment as the moment in a member rather than a resisting moment acting on the member. This, of course, reverses the signs of the end moments from those used by Professor Wilson.

FIG. 20.—BEAM COEFFICIENTS

Table 1 gives the effect of applying a positive (clockwise) moment to each joint of the frame, without sidesway. The table may be computed by moment distribution. The writer, however, prefers the traverse method (22). For a moment at joint B the traverse is shown in Fig. 21. The moments on the diagram are multiplied by $\frac{1,000}{903.97}$ to obtain the results for joint B in Table 1. A corresponding traverse must be run for joint F. The intermediate joints, C, D, and E are easily calculated by using data taken from the two traverses already run. Table 1 will apply to any combination of fixed-end moments that may act on the frame.

When the frame is permitted to deflect as indicated in Fig. 22(*a*), the relative displacements of the members AB, BC, and CD are shown in Table 2. In the triangle abc, side ab is drawn normal to member AB, side bc normal to member BC, and, likewise, side ca normal to member CD. These displacements are d, $-0.8\,d$, and $0.6\,d$, respectively. The equations for fixed-end moments, corresponding to $M'_{AB} = M'_{BA} = 6\,E\,K\,\frac{d}{L}$ for uniform moment of inertia members, are as follows:

FIG. 21.—SOLUTION BY TRAVERSE METHOD

$$M_L = \frac{E\,I\,d}{(1 - u - v)\,p\,L^2} \qquad \text{(45a)}$$

and

$$M_R = \frac{E\,I\,d}{(1 - u - v)\,q\,L^2} \qquad \text{(45b)}$$

Table 2 shows the fixed-end moments for members AB, BC, CD, and DH, Fig. 19. Member DE is like member BC, member EF is like member CD, and member FG is like member BA.

There are three conditions of deformation for this frame. The first condition is shown in Fig. 22(*a*). The coefficients of $E\,d$, as calculated in Table 2, have been multiplied by 1,000 arbitrarily to place the decimal point in a more convenient location. The fixed-end moment coefficients of $\frac{E\,d_1}{1{,}000}$ for members AB, BC, and CD are placed on the diagram in their respective locations and the moments are balanced by the use of Table 1. Thus, at joint B, $204.12 - 128.75 = 75.37$, a clockwise moment which must be balanced throughout the frame. Therefore, $\frac{75.37}{1{,}000}$ times the values in Table 1 for joint B will be added algebraically to the respective end moments of the members. Likewise, at joint C, $-75.40 + 31.81 = -43.59$, the unbalanced moment, and

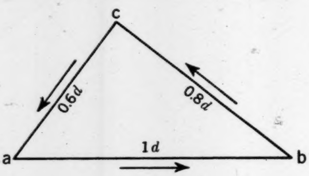
FIG. 22

TABLE 2.—RELATIVE DISPLACEMENTS AND MOMENTS, MEMBERS AB, BC, CD, AND DH, FIG. 19



Member	Displacements	Moments
AB		$M_{BA} = \frac{d \times E \times 2}{0.573 \times 0.171 \times 100} = 0.20412\ E\,d$
BC		$M_{CB} = \frac{-0.8\,d \times E \times 2}{0.323 \times 0.292 \times 225} = -0.07540\ E\,d$ $M_{BC} = \frac{-0.8\,d \times E \times 2}{0.323 \times 0.171 \times 225} = -0.12875\ E\,d$
CD		$M_{CD} = \frac{0.6\,d \times E \times 2}{0.323 \times 0.292 \times 400} = 0.03181\ E\,d$ $M_{DC} = \frac{0.6\,d \times E \times 2}{0.323 \times 0.171 \times 400} = 0.05432\ E\,d$
DH		$M_{DH} = \frac{d \times E \times 2}{0.323 \times 0.171 \times 144} = 0.25146\ E\,d$ $M_{HD} = \frac{d \times E \times 2}{0.323 \times 0.292 \times 144} = 0.14726\ E\,d$

$\frac{-43.59}{1,000}$ times the moments shown for a +1,000 ft-lb moment at joint C in Table 1 will spread this unbalanced moment throughout the frame. The same procedure is followed for the unbalanced +54.32 moment at joint D. The end moments for each member are now added and the first condition of deformation is finished.

FIG. 23

Fig. 22(*b*) shows the second condition of deformation, and the coefficients of $\frac{E\,d_2}{1,000}$ are computed as before. The third condition is solved in Fig. 22(*c*).

In Fig. 23 and the remainder of this discussion, the expressions $\frac{E\,d_1}{1,000}$, $\frac{E\,d_2}{1,000}$, and $\frac{E\,d_3}{1,000}$ have been contracted to d_1, d_2, and d_3, respectively.

From Fig. 23(*a*) it is evident that

$$H_1 + H_2 + H_3 = 700 \qquad \textbf{(46a)}$$

In Fig. 23(*b*), from $\Sigma M = 0$,

$$H_1 = 14.918\, d_1 + 8.479\, d_2 + 8.225\, d_3 \qquad \textbf{(46b)}$$

Similarly, in Fig. 23(*c*),

$$H_2 = -3.682\, d_1 + 25.38\, d_2 + 19.434\, d_3 \qquad \textbf{(46c)}$$

and, in Fig. 23(*d*),

$$H_3 = -0.173\, d_1 - 4.652\, d_2 + 6.949\, d_3 \qquad \textbf{(46d)}$$

Substituting Eqs. 46*b*, 46*c*, and 46*d* in Eq. 46*a* gives

$$11.063\, d_1 + 29.207\, d_2 + 34.608\, d_3 = 700 \qquad \textbf{(46e)}$$

From Fig. 23(*e*),

$$H_4 - H_3 = 0 \qquad \textbf{(47a)}$$

In Fig. 23(*f*), taking moments about point F,

$$V_4 = 600 - 0.834\, d_1 - 4.313\, d_2 - 5.682\, d_3 \qquad \textbf{(47b)}$$

In Fig. 23(*g*), taking moments about point E and substituting the value of V_4 from Eq. 47*b*,

$$H_4 = 480 + 1.560\, d_1 + 14.026\, d_2 + 1.552\, d_3 \qquad \textbf{(47c)}$$

Substituting Eqs. 46*d* and 47*c* in Eq. 47*a* gives

$$480 + 1.733\, d_1 + 18.678\, d_2 - 5.397\, d_3 = 0 \qquad \textbf{(47d)}$$

From Fig. 23(*h*),

$$H_1 + H_5 = 700 \qquad \textbf{(48a)}$$

In Fig. 23(*i*), taking moments about point B,

$$V_5 = 456 + 3.739\, d_1 + 4.452\, d_2 + 5.484\, d_3 \qquad \textbf{(48b)}$$

In Fig. 23(*j*), taking moments about point C and substituting the value of V_5 from Eq. 48*b* gives the equation,

$$H_5 = 608 + 14.095\, d_1 + 4.307\, d_2 + 2.838\, d_3 \qquad \textbf{(48c)}$$

Substituting Eqs. 46*b* and 48*c* in Eq. 48*a* gives

$$29.013\, d_1 + 12.786\, d_2 + 11.063\, d_3 = 92 \qquad \textbf{(48d)}$$

Solving Eqs. 46*e*, 47*d*, and 48*d* simultaneously gives $d_1 = -3.062$, $d_2 = -15.512$, and $d_3 = 34.280$.

The moments in Figs. 22(*a*), 22(*b*), and 22(*c*) multiplied by their respective *d*-values are shown in Table 3. The final values of the moments at the ends of all members are given in the bottom line of Table 3.

Additional bays can be added to the frame in Fig. 19 without increasing the problem unduly. Each additional bay would add one more condition of deformation. In other words, such a three-bay structure would require four conditions of deformation; a four-bay structure would call for five; etc.

The solution of this type of problem by superposition may be rather long, but the individual steps are logical and easily followed and in the end a difficult problem has been solved.

JAROSLAV POLIVKA,[10] M. AM. SOC. C. E.—The principle of superposition is generally recommended and used in cases in which the direct analysis either involves the solution of a greater number of simultaneous equations or requires a relatively tedious determination of certain constants of the structure. For example, using the slope-deflection method, the examples presented in the paper require the solution of the following number of simultaneous equations:

Example No.	Number of equations	Example No.	Number of equations
1	3	5	8
2	4	6	3
3	4	7	4
4	6	8	5

In Examples 3 and 7, there are only four equations, of course, since the frames are symmetrical.

In most cases several load systems must be investigated, and for this reason preference should be given to a method of analysis by which certain constant values or characteristics of the given structure, common and applicable to any type of loading, can be determined. The method of analysis presented by the author possesses this advantage, since the computation of the internal forces (bending moments, shears, and thrusts) produced by lateral displacements of the joints is treated independently of transverse load.

Since an accuracy greater than 4% is usually not required for design purposes (except for checking the more complicated statically indeterminate structures), graphical or combined methods are useful for types of framed structures to which the method of superposition is applicable. One of the most promising methods is that of fixed (characteristic) points, which has not yet been fully utilized in the United States. The solution is general and can be applied to hinged and elastically yielding supports. The latter condition (yielding supports) is often more serious in engineering practice than either of the extreme conditions of fully restrained or hinged supports.

---

[10] Research Associate, Univ. of California, Cons. Engr., Kaiser Co., Berkeley, Calif.

The designer can adapt graphical, semigraphical, or algebraic processes to his purpose. Graphical devices are quicker; they are easier to check; and they are as accurate as the precision of the draftsman who prepares them.

A graphical solution by fixed points, applied to Example 2, is demonstrated by reference to Fig. 24. The determination of the fixed (characteristic) points, U and V, of each structural member is shown in Fig. 24(*a*) using the values of the elastic weights, $G = \frac{L}{E\,I} = \frac{1}{E\,K}$, and the angular displacements, δ of the joints. The distances of the characteristic points, u and v, can be checked or calculated by the following relationships: $u_1 = \frac{L_1}{3}$ (full restraint at point A); $u_2 = \frac{L_2}{3}\,\frac{G_2}{G_2 + 2\,\delta_{BA}}$; and $u_4 = \frac{L_4}{3}\,\frac{G_4}{G_4 + 2\,\delta_{CAD}}$, in which $\delta_{CAD} = \frac{\delta_{CA}\,\delta_{CD}}{\delta_{CA} + \delta_{CD}}$, etc. The angular displacement δ_{BA} has the significance of the elastic weight of support of the member BC at point B and equals $\frac{G_1}{4}$, because of restraint at point A. The successive angular displacements can be expressed in terms of distances between the opposite fixed points and the supports; for example, $\delta_{CA} = \frac{G_2}{6}\left(3 - \frac{L_2}{L_2 - u_2}\right)$, etc.

Fig. 24(*b*) shows the bending moments of the bent, subjected to a central load on member BC, without considering the sidesway, found by the fixed points and the crosslines for the loaded span. The crosslines are determined by values K_B and K_C, derived from fixed-end moments or from formulas for each type of transverse loading.

To take the lateral displacement of the column into account, the shears H_1, H_2, and H_3 are calculated from the moment diagram, and the sum, ΣH, of opposite sign, is applied at the temporary support, point E. The effect of this temporary reaction is obtained by allowing arbitrary translations $\Delta_B = \Delta_C = \Delta_E$ of the columns and calculating the shear in each column. The shear $H_{1\Delta}$ produced by translation Δ_B is calculated from $\Delta_B = H_{1\Delta}\,G'_1\,r^2_1$, in which G'_1 is the total elastic weight of column AB, restrained at point A and elastically supported at point B, and r_1 is the semiaxis of the ellipse of elasticity of this column. The elastic centroid and r_1 are found graphically as shown in Fig. 24(*c*). Simple relationships permit the computation of moments at points B and A, produced by $H_{1\Delta}$, as follows:

$$\bar{M}_{BA} = \frac{6\,\Delta_B\,v_1}{L_1\,G_1\,(L_1 - u_1 - v_1)}\ldots\ldots\ldots\ldots\ldots\ldots(49)$$

and

$$\bar{M}_{AB} = -\,\frac{6\,\Delta_B\,u_1}{L_1\,G_1\,(L_1 - u_1 - v_1)} = -\,M_{BA}\,\frac{u_1}{v_1}\ldots\ldots\ldots\ldots(50)$$

The moment $\bar{M}_{BA}$ is then distributed over all remaining structural members. Similarly, the moments due to $H_{2\Delta}$ and $H_{3\Delta}$, which are produced by $\Delta_C = \Delta_E$

(*c*) DETERMINATION OF ELASTIC CENTROID

FIG. 24.—GRAPHICAL SOLUTION OF EXAMPLE 2

$= \Delta_B$, are calculated. Finally, all moments produced by equal lateral displacement of the columns are summed up and the corresponding shear along member BCE is calculated.

Substituting the values in Eqs. 49 and 50: $\bar{M}_{BA} = \frac{182}{710}$ and $\bar{M}_{AB} = -\frac{233}{710}$. The moment $\bar{M}_{BA}$ is distributed to the other joints using the final carry-over factors which are determined by fixed points and angular displacements (at the joint C). The carry-over factor from point B to point C is $C_{BC} = \frac{v_2}{L_2 - v_2} = \frac{29}{91}$; the carry-over factor $\frac{M_{CD}}{M_{CB}} = \frac{11}{29}$; the carry-over factor $\frac{M_{CE}}{M_{CB}} = \frac{18}{29}$, etc. Similarly, the values $\bar{M}_{CD} = \frac{218}{710}$ and $\bar{M}_{DC} = -\frac{251}{710}$ (for column DC) and $\bar{M}_{EF} = \frac{112}{710}$ (for column FE) are obtained and carried over to the other joints (Fig. 24(*c*)). For the purpose of superposition, only the ratio between the temporary reaction at point E (Fig. 24(*b*)) and the total shear along member ECB (or the total thrust along this member) are considered. Therefore, the common denominator 710 can be eliminated (Fig. 24(*c*)). The temporary reaction at point E is $\frac{39}{284 \times 15} M$ (Fig. 24(*b*)) and the total shear produced by sidesway is $\frac{1{,}074}{15}$; hence, the ratio sought is $\frac{39 \times 5{,}000}{284 \times 1{,}074} = 0.63934$.

The additional moments produced by sidesway are calculated by multiplying the values in Fig. 24(*c*) by the ratio 0.63934.

Professor Wilson uses the moment distribution method (except in Example 1, in which the slope-deflection method is used) for the determination of the superimposing effects. The relative accuracy depends on the number of cycles and is usually completely sufficient for a rational design as shown by the values obtained by the author as compared with more accurate results of the writer's computations by the method of fixed (characteristic) points:

Example	Moments
2	$M_{AB} = 390$ (391.05); $M_{BA} = 963$ (963.68); $M_{CB} = 2{,}135$ (2,136.88); $M_{CD} = -933$ (−935.76); $M_{DC} = -557$ (−558.67); $M_{CE} = -1{,}202$ (1,201.11); and $M_{EC} = -137$ (−139.86).
4	$M_{AB} = -2{,}838$ (−2,831.37); $M_{BA} = -2{,}345$ (−2,325.14); $M_{CD} = -1{,}612$ (−1,612.93); $M_{DC} = -799$ (−808.81); $M_{DE} = -1{,}407$ (−1,403.79); $M_{ED} = -1{,}954$ (−1,955.97); $M_{DF} = 2{,}203$ (2,212.61); $M_{FG} = -1{,}109$ (−1,112.61); and $M_{GF} = -1{,}111$ (−1,112.14).
5	$M_{AB} = 8.71$ (8.79); $M_{BA} = 14.58$ (14.65); $M_{CB} = 2.70$ (2.82); $M_{CD} = 4.06$ (3.92); $M_{DC} = 6.30$ (6.31); $M_{ED} = -7.75$ (−7.75); $M_{FE} = 12.15$ (12.02); $M_{CF} = -6.76$ (−6.74); $M_{FC} = -2.66$ (−2.64); $M_{FA} = -9.49$ (−9.38); and $M_{AF} = -8.71$ (−8.79).

Example	Moments
6	M_{AB} = 228 (230.93); M_{BA} = 428 (429.18); M_{CB} = 640 (642.25); and M_{DC} = − 304 (−304.79).
7	M_{AB} = − 472 (−474.36); M_{BA} = − 433 (−433.76); M_{BE} = − 134 (−135.19); M_{EB} = − 308 (−307.40); and M_{BC} = 569 (568.95).
8	M_{AB} = 6,970 (6,986.53); M_{BA} = 3,740 (3,746.31); M_{CD} = 2,250 (2,256.11); M_{DC} = 550 (539.99); and M_{ED} = 3,800 (3,831.97).

In the foregoing, the writer's values are in parentheses. The results are accurate, the differences being less than 4%. In Example 3, no differences were found.

ODD ALBERT,[11] ASSOC. M. AM. SOC. C. E.—Structural analysis by superposition, as proposed by Professor Wilson, is an excellent method. An improvement in procedure, however, is suggested by Example 2, an unsymmetrical three-column bent subjected to an off-center vertical load. The author solves this frame by determining the moment caused directly by the vertical load and then adjusts for the effect of sidesway in a separate operation. Final moments are obtained by adding the two sets of moments. A suggestion that results in more simple mathematics and one that is easier to visualize is presented herein, adapting the principle of slope deflection, as applied to a cantilever beam. For this purpose the deflections of the free end of a cantilever beam under various loadings are given in Fig. 25.

The sign conventions preferred by the writer are illustrated in Fig. 26—that is, when the end moment is negative, the arrow is drawn clockwise.

Vertical Load on Span BC.—If span BC, Fig. 27, is loaded as shown with the frame fixed to prevent sidesway, the moment transmitted to joint B travels to point A, and the moment transmitted to joint C separates and travels through point E to point F.

Referring to column EF, Fig. 27, the angle θ_E causes a deflection of $\theta_E L_{EF}$ at F_1, and the horizontal force H_F causes a deflection in the opposite direction (see Fig. 25):

$$\theta_E L_{EF} - \frac{H_F L^2_{EF}}{3 E} = 0 \tag{51}$$

Since $H_F = \dfrac{M_E}{L_{EF}}$,

$$\theta_E = \frac{M_{EF}}{3 E} = - \frac{M_{EC}}{3 E} \tag{52}$$

Referring next to beam CE, Fig. 27, if end C were free to deflect:

$$\theta_E L_{CE} + \frac{V_C L^2_{CE}}{3 E \times 2} + \frac{M_{CE} L_{CE}}{2 E \times 2} = 0 \tag{53}$$

---

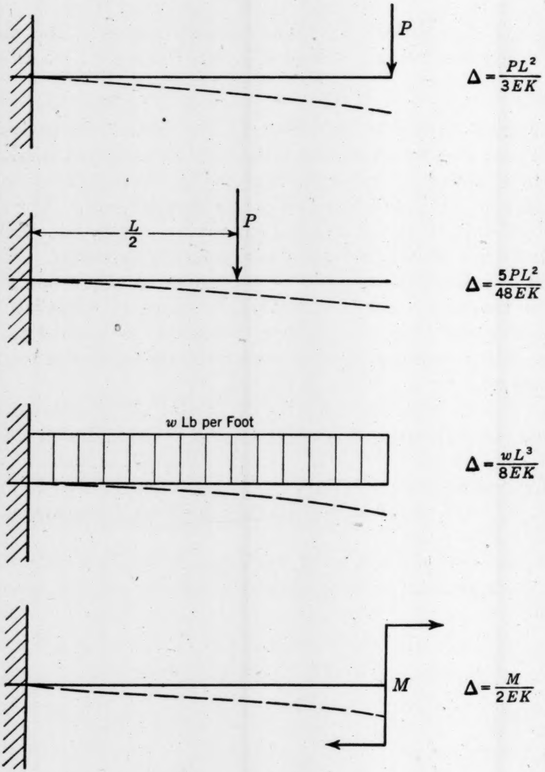
[11] Structural Engr., Belmar, N. J.

Substituting $V_C = -\frac{M_{CE}}{L_{CE}} - \frac{M_{EC}}{L_{CE}}$,

$$M_{EC} = \frac{M_{CE}}{6} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (54)$$

In the same beam, if end E is free to deflect:

$$\theta_C\, L_{CE} + \frac{V_E\, L^2_{CE}}{3\,E \times 2} + \frac{M_{EC}\, L_{CE}}{2\,E \times 2} = 0 \ldots\ldots\ldots\ldots (55)$$



P
$\Delta = \frac{PL^2}{3EK}$
$\frac{L}{2}$
P
$\Delta = \frac{5PL^2}{48EK}$
w Lb per Foot
$\Delta = \frac{wL^3}{8EK}$
M
$\Delta = \frac{M}{2EK}$

Fig. 25

In this case,

$$V_E = -\frac{M_{CE}}{L_{CE}} - \frac{M_{EC}}{L_{CE}} = -\frac{7\,M_{CE}}{6\,L_{CE}} \ldots\ldots\ldots\ldots (56)$$

Substituting Eq. 56 in Eq. 55 and solving for θ_C:

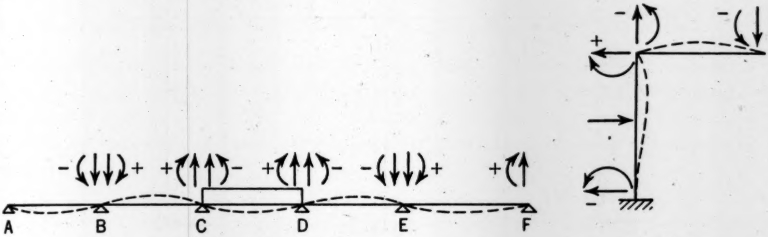
$$\theta_C = \frac{11\,M_{CE}}{72\,E} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (57)$$

Column DC is treated similarly. Assuming point C free to deflect:

$$\frac{H_C\,L^2_{CD}}{3\,E} + \frac{M_{ED}\,L_{CD}}{2\,E} = 0 \quad \text{(58)}$$

Substituting $H_C = -\frac{M_{CD}}{L_{CD}} - \frac{M_{DC}}{L_{CD}}$,

$$M_{DC} = \frac{M_{CD}}{2} \quad \text{(59)}$$



(a) HORIZONTAL BEAM (b) VERTICAL BEAM

FIG. 26.—SIGN CONVENTIONS

Assuming point D free to deflect, similarly:

$$\theta_C\,L_{CD} + \frac{H_D\,L^2_{CD}}{3\,E} + \frac{M_{DC}\,L_{CD}}{2\,E} = 0 \quad \text{(60)}$$

With $H_D = -\frac{M_{CD}}{L_{CD}} - \frac{M_{DC}}{L_{CD}}$:

$$\theta_C = \frac{M_{CD}}{4\,E} \quad \text{(61)}$$

Since each member meeting at joint C rotates through an angle θ_C, Eqs. 57 and 61 must be equal; that is, $\frac{11\,M_{CE}}{72\,E} = \frac{M_{CD}}{4\,E}$ and

$$M_{CD} = \frac{11\,M_{CE}}{18} \quad \text{(62)}$$

Distribute the moment M_{CB} to beam CE and column CD as M_{CE} and M_{CD}, respectively. In other words, since $M_{CB} = M_{CE} - M_{CD} = -M_{CE} - \frac{11\,M_{CE}}{18} = -\frac{29}{18}\,M_{CE}$,

$$M_{CE} = -\frac{18}{29}\,M_{CB} \quad \text{(63a)}$$

and

$$M_{CD} = -\frac{11\,M_{CE}}{18} = -\frac{11}{18} \times \frac{18\,M_{CB}}{29} = -\frac{11\,M_{CB}}{29} \quad \text{......(63b)}$$

Finally (see Eqs. 57 and 61),

$$\theta_C = -\frac{11\,M_{CB}}{116\,E} = \frac{M_{CD}}{4\,E} = \frac{11\,M_{CE}}{72\,E} \quad \text{..............(64)}$$

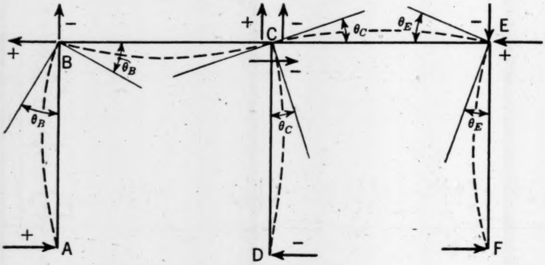


Fig. 27.—Vertical Load on a Frame Fixed Against Sidesway

Because column AB is identical to column CD, $M_{AB} = \frac{M_{BA}}{2}$, and:

$$\theta_B = \frac{M_{AB}}{4\,E} = -\frac{M_{BC}}{4\,E} \quad \text{..................(65)}$$

If beam BC is free to deflect at end C (compare Eq. 53):

$$\theta_B\,L_{BC} + \frac{5\,P\,L^2_{BC}}{48\,E \times 2} + \frac{M_{CB}\,L_{BC}}{2\,E \times 2} - \frac{V_C\,L^2_{BC}}{3\,E \times 2} = 0 \quad \text{........(66)}$$

Substituting $V_C = \frac{P}{2} + \frac{M_{BC}}{L_{BC}} + \frac{M_{CB}}{L_{BC}}$:

$$-5\,M_{BC} + M_{CB} = \frac{3\,P\,L_{BC}}{8} = 7{,}500 \quad \text{.............(67)}$$

If beam BC is free to deflect at end B, an equation similar to Eq. 66 $\left(\text{substituting } V_B = \frac{P}{2} - \frac{M_{BC}}{L_{BC}} - \frac{M_{CB}}{L_{BC}}\right)$ yields:

$$-91\,M_{CB} + 29\,M_{BC} = -\frac{3\,P\,L_{BC}}{8} \times 29 = -7{,}500 \times 29 \quad \text{....(68)}$$

Solving Eqs. 67 and 68 simultaneously: $M_{BC} = -\frac{77{,}500}{71}$; $M_{CB} = +\frac{145{,}000}{71}$;

$M_{BA} = +\frac{77{,}500}{71}$; $M_{AB} = \frac{M_{BA}}{2} = \frac{1}{2} \times \frac{77{,}500}{71} = +\frac{38{,}750}{71}$; M_{CD} (Eq. 63*b*) $= -\frac{55{,}000}{71}$; M_{DC} (Eq. 59) $= -\frac{27{,}500}{71}$; M_{CB} (Eq. 63*a*) $= -\frac{90{,}000}{71}$; M_{BC} (Eq. 54) $= -\frac{15{,}000}{71}$; and $M_{EF} = +\frac{15{,}000}{71}$.

The horizontal force H_B is equal to $\frac{38{,}750 + 77{,}500}{71 \times 15} = \frac{7{,}750}{71}$. Similarly, $H_C = -\frac{5{,}500}{71}$ and $H_E = +\frac{1{,}000}{71}$. The horizontal force at the top required to prevent horizontal movement, then, is the sum of the three, or $\frac{3{,}250}{71}$.

Sidesway.—When columns are of equal height, the sidesway, or lateral deflection of the horizontal members, is equivalent to the corresponding lateral displacement of the column bases, assuming the girders to be fixed. The problem is approached by analyzing the effect of moving each column base separately.

For example (see Fig. 28), if support A is moved to the left a distance Δ, the moment generated in joint B will be distributed along the two paths

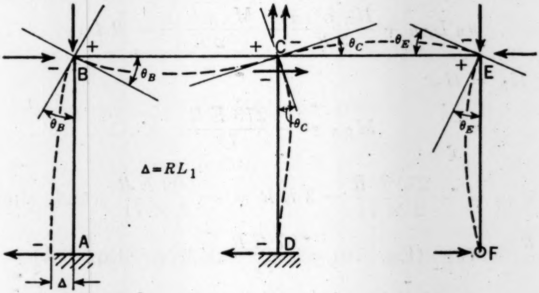

FIG. 28.—SUPPORT A MOVED TO THE LEFT A DISTANCE Δ

C-E-F and C-D. By Eq. 64, $\theta_C = -\frac{11\, M_{CB}}{116\, E}$ in terms of beam BC. If this beam is cut at end B,

$$\theta_C\, L_{BC} - \frac{V_B\, L^2_{BC}}{3\, E \times 2} + \frac{M_{BC}\, L_{BC}}{2\, E \times 2} = 0 \quad \text{..............} (69)$$

As before, substituting $V_B = \frac{M_{BC}}{L_{BC}} + \frac{M_{CB}}{L_{BC}}$:

$$M_{CB} = \frac{29\, M_{BC}}{91} \quad \text{........................} (70)$$

Conversely, if joint B rotates with end C cut:

$$\theta_B L_{BC} - \frac{V_C L^2_{BC}}{3 E \times 2} + \frac{M_{CB} L_{BC}}{2 E \times 2} = 0 \ldots\ldots\ldots\ldots (71)$$

Substituting $V_C = V_B$, Eq. 71 becomes:

$$\theta_B = \frac{51 M_{BC}}{4.91 E} = -\frac{51 M_{BA}}{4.91 E} \ldots\ldots\ldots\ldots (72)$$

Isolate column AB, cut end B, and rotate support A, then:

$$\frac{H_B L^2_{AB}}{3 E} + \frac{M_{BA} L_{AB}}{2 E} = R L_{AB} \ldots\ldots\ldots\ldots (73)$$

Substituting $H_B = -\frac{M_{AB}}{L_{AB}} - \frac{M_{BA}}{L_{AB}}$:

$$M_{AB} = \frac{M_{BA}}{2} - 3 E R \ldots\ldots\ldots\ldots (74)$$

Conversely, with end A cut:

$$\theta_B L_{AB} + \frac{H_A L^2_{AB}}{3 E} + \frac{M_{AB} L_{AB}}{2 E} = R L_{AB} \ldots\ldots\ldots\ldots (75)$$

Substituting $H_A = H_B$:

$$M_{BA} = -\frac{273 E R}{71} \ldots\ldots\ldots\ldots (76)$$

Therefore: $M_{AB} = -\frac{273 E R}{2 \times 71} - 3 E R = -\frac{699 E R}{2 \times 71}$; and, similarly: $M_{BC} = +\frac{273 E R}{71}$; M_{CB} (Eq. 70) $= \frac{87 E R}{71}$; M_{CD} (Eq. 63*b*) $= -\frac{33 E R}{71}$; M_{DC} (Eq. 59) $= -\frac{33 E R}{2 \times 71}$; M_{CE} (Eq. 63*a*) $= -\frac{54 E R}{71}$; M_{EC} (Eq. 54) $= -\frac{9 E R}{71}$; and $M_{EF} = +\frac{9 E R}{71}$.

Deflecting support D to the left a distance Δ yields, by the same general procedure: $M_{CD} = -\frac{327 E R}{71}$; $M_{DC} = -\frac{327 E R}{2 \times 71} - 3 E R = -\frac{753 E R}{2 \times 71}$; $M_{CB} = +\frac{55 \times 327 E R}{109 \times 71} = +\frac{165 E R}{71}$; $M_{BC} = \frac{1 \times 165 E R}{5 \times 71} = +\frac{33 E R}{71}$; $M_{BA} = -\frac{33 E R}{71}$; $M_{AB} = -\frac{33 E R}{2 \times 71}$; $M_{CE} = \frac{54}{109} \times \frac{327 E R}{71} = \frac{162 E R}{71}$; M_{EC} (Eq. 54) $= \frac{1}{6} \times \frac{162 E R}{71} = \frac{27 E R}{71}$; and $M_{EF} = -\frac{27 E R}{71}$.

Finally, deflecting support F a distance Δ to the left, and solving as before:

$$M_{EF} = -\frac{150\,E\,R}{71}\,;\ M_{EC} = +\frac{150\,E\,R}{71}\,;\ M_{CE} = \frac{8}{25} \times \frac{150\,E\,R}{71} = \frac{48\,E\,R}{71}\,;$$

$$M_{CD} = -\frac{3}{8} \times \frac{48\,E\,R}{71} = -\frac{18\,E\,R}{71}\,;\quad M_{DC}\ \ (\text{Eq. } 59) = -\frac{1}{2} \times \frac{18\,E\,R}{71}$$

$$= -\frac{9\,E\,R}{71}\,;\quad M_{CB} = -\frac{5}{8} \times \frac{48\,E\,R}{71} = -\frac{30\,E\,R}{71}\,;\quad M_{BC} = -\frac{1}{5} \times \frac{30\,E\,R}{71}$$

$$= -\frac{6\,E\,R}{71}\,;\ M_{BA} = +\frac{6\,E\,R}{71}\,;\ \text{and } M_{AB} = \frac{1}{2} \times \frac{6\,E\,R}{71} = +\frac{3\,E\,R}{71}\,.$$

The moments caused by a sidesway of Δ will then be equal to the sum of the moments generated by the separate movements of the supports; that is,

$$\left.\begin{array}{c} M_{AB} = -\dfrac{363\,E\,R}{71}\,;\ M_{BA} = -\dfrac{300\,E\,R}{71}\,;\ M_{DC} = -\dfrac{402\,E\,R}{71}\,; \\ M_{CD} = -\dfrac{378\,E\,R}{71}\,;\ \text{and } M_{EF} = -\dfrac{168\,E\,R}{71} \end{array}\right\} \ldots (77)$$

By adding up the end column moments $\left(\frac{1{,}611\,E\,R}{71}\right)$, the horizontal force at the top of the frame required to move it sidewise a distance Δ will be $\frac{1{,}611\,E\,R}{71 \times 15}$ lb; but this force has already been found equal to $\frac{3{,}250}{71}$ lb (see text following Eq. 68). Equating the two quantities: $E\,R = \frac{16{,}250}{537}$ lb, a value that can be substituted in Eqs. 77.

The final moments are obtained by adding the moments caused by the vertical load (following Eq. 68) and those caused by sidesway; thus: $M_{AB} = +\frac{38{,}750}{71} - \frac{363 \times 16{,}250}{71 \times 537} = \frac{2{,}500 \times 28}{179}$. Similarly, $M_{BA} = +\frac{2{,}500 \times 69}{179}$; $M_{DC} = -\frac{2{,}500 \times 40}{179}$; $M_{CD} = -\frac{2{,}500 \times 67}{179}$; and $M_{EF} = +\frac{2{,}500 \times 10}{179}$.

Summary.—The writer can offer no criticism of the basic thesis presented by Professor Wilson. The foregoing comments are offered merely in the hope of suggesting an improvement in the complete procedure.

W. C. SPIKER,[12] M. AM. SOC. C. E.—As the author states (see heading, "Synopsis"), in textbooks on structural analysis the application of the principle of superposition is not emphasized as much as its importance warrants. The writer has studied only one of the examples in the paper—Example 1. To that demonstration he wishes to suggest the following simplification: Omit

---

[12] Engr. Adviser, Public Bldgs. Administration, Federal Works Agency, Washington, D. C.

Eqs. 5*a* and 5*b* of the simultaneous solution and proceed thus (omitting E for the sake of brevity):

At joint B—

$$4\,\theta_B - 6\,R + 20\,\theta_B + 10\,\theta_C = 24\,\theta_B - 6\,R + 10\,\theta_C = 0 \quad \ldots\ldots (78)$$

Therefore,

$$\theta_B = 0.25\,R - 0.417\,\theta_C \quad \ldots\ldots (79)$$

At joint C

$$20\,\theta_C + 10\,\theta_B + 8\,\theta_C - 8\,R = 0 \quad \ldots\ldots (80)$$

In Eq. 81, substituting the value of θ_B from Eq. 80, and simplifying,

$$23.83\,\theta_C - 5.5\,R = 0 \quad \ldots\ldots (81)$$

From the foregoing it appears to the writer that when practicable it is much simpler to substitute the value of θ from each preceding joint in the next succeeding equation than to carry "unknowns" through the fundamental equations and then write new equations and solve for the "unknowns."

DAVID B. HALL,[13] ASSOC. M. AM. SOC. C. E.—A simple orderly procedure for analyzing rigid frames with sidesway is presented in this paper. It is instructive to observe that relations exist between step 1, in which the geometrical properties of the cells are established, and step 4, in which conditions of equilibrium are established. It is the purpose of this discussion to point out these relations and to show that in the case of a single cell nonrectangular quadrangular frame they may be of considerable use.

In any structure the geometrical properties and static properties are closely interrelated through the law of conservation of energy. Thus, in most cases geometric methods and static methods are very similar, but because the relationship is an inverse one there will be occasions when the two are not equally simple. For example, the static analysis of a truss by vector diagram is simpler than the geometric analysis by Williot diagram because in the former all lines are parallel to members, whereas in the latter there are lines both parallel and perpendicular to members.

In the case of the quadrangular frame, an examination of the paper discloses that the statical analysis (Eqs. 22 to 25) requires a piecemeal method of approach, as contrasted with the simple geometric relation (Eq. 20). This difference appears to be characteristic of quadrangular cells. It seems logical, therefore, to apply the law of conservation of energy to geometric relations for the static analysis of the problem, just as it has been found advantageous to apply this law (as the method of virtual work) to find deflections of trusses from statical relations.

Before proceeding to do this, it will be advantageous to reestablish the geometrical relations in a manner slightly different from Eq. 20. When one side of a quadrangular cell remains fixed (AD, Fig. 29), the ends of the opposite member (BC) are constrained to move at right angles to their respective connecting members (AB and CD), and the member rotates about an instantaneous center located at the intersection of the connecting members (point O). In this connection it may be convenient to visualize triangle BCO as an imaginary rigid body supported on the two legs. If this imaginary body is given a rotation R_0, then:

---

[13] Stress Analyst, Otis Elevator Co., New York, N. Y.

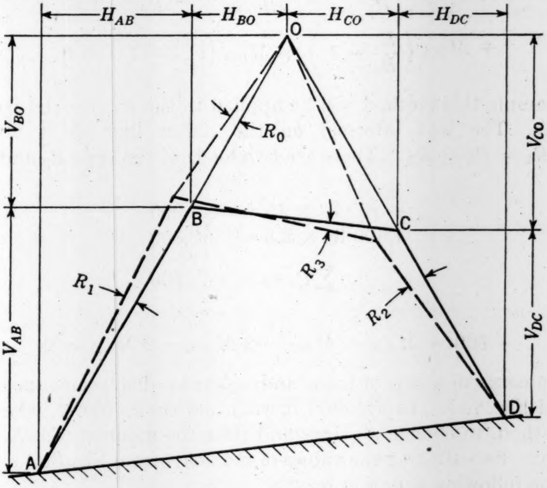

FIG. 29.—DEFORMATION OF A QUADRANGLE REFERRED TO INSTANTANEOUS CENTER

$$R_3 = R_0 \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (82a)$$

$$R_1 = -R_0 \frac{\overline{BO}}{\overline{AB}} = -R_0 \frac{V_{BO}}{V_{AB}} = -R_0 \frac{H_{BO}}{H_{AB}} \ldots\ldots\ldots (82b)$$

and

$$R_2 = -R_0 \frac{\overline{CO}}{\overline{DC}} = -R_0 \frac{V_{CO}}{V_{DC}}$$

$$= -R_0 \frac{H_{CO}}{H_{DC}} \ldots\ldots\ldots\ldots (82c)$$

Thus, the rotations of the various members are quite simply expressed in terms of a single parameter R_0.

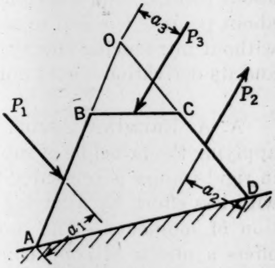

FIG. 30.—NOTATION FOR LOADS ON A QUADRANGULAR FRAME

Energy equations can now be written. For notation relating to loads refer to Fig. 30. Apply a rotation R_0 at the instantaneous center. The work done by loads on member BC equals P_3 a_3 R_0. The work done by loads on the legs equals $P_1 a_1 R_1$ and $P_2 a_2 R_2$. The work done by moments at A and D equals $M_{AB} R_1$ and $M_{DC} R_2$. The work done by moments at B and C equals

M_{BA} $(R_1 - R_3)$ and M_{CD} $(R_2 - R_3)$. Summing up the work done by all items and dividing by R_0,

$$P_3\,a_3 + P_1\,a_1\frac{R_1}{R_0} + P_2\,a_2\frac{R_2}{R_0} + M_{AB}\frac{R_1}{R_0} + M_{DC}\frac{R_2}{R_0}$$
$$+ M_{BA}\left(\frac{R_1}{R_0} - 1\right) + M_{CD}\left(\frac{R_2}{R_0} - 1\right) = 0 \ldots\ldots\ldots\ldots (83)$$

As an example this method will be applied to the trapezoidal frame shown in Fig. 8(*a*). The legs intersect on the center line 15 ft above BC— $- R_1 = - R_2 = R_3 = R_0$. There are two loads of the type P_3 and no others; thus—

$$\begin{array}{rr} -\ 200 \text{ lb} \times 15 = & -\ 3{,}000 \\ 1{,}000 \text{ lb} \times 2.5 = & 2{,}500 \\ \hline \sum P_3\,a_3 = & -\quad 500 \end{array}$$

and

$$- 500 - M_{AB} - M_{DC} - 2\,M_{BA} - 2\,M_{CD} = 0 \ldots\ldots\ldots\ldots (84)$$

Values of moments in terms of loads and unknown displacements are given in Fig. 8(*b*) and Fig. 8(*c*). In Fig. 8(*c*) it would be more orderly, when using the proposed method, to change all signs and refer the moments to R_0, but this is not necessary. Substituting the values of moments from Fig. 8(*b*) and Fig. 8(*c*) in Eq. 84, the following equation results:

$$- 500 - (194 - 6.46\,E\,R_1) - (- 338 - 6.46\,E\,R_1)$$
$$- 2\,(391 - 6.92\,E\,R_1) - 2\,(- 677 - 6.92\,E\,R_1) = 0 \ldots\ldots (85)$$

Solving Eq. 85, $E\,R_1 = - 5.32$, which agrees with the author's value.

After Eq. 83 has been derived by energy methods, it is not very difficult to retrace the solution and discover the significance of Eq. 83 as an equilibrium equation: Each term of the equation can be shown to represent a moment about point O, and the equation therefore is a statement that the net moment about point O is equal to zero. Thus, the equation could have been obtained without introducing energy, but its discovery would not have been so obvious and its derivation would not have been so simple.

A. A. Eremin,[14] Assoc. M. Am. Soc. C. E.—An interesting method of applying the principle of superposition to the algebraic distribution of moments in rigid frames is presented in this paper. The same results can be obtained, with less effort, by applying superposition principles to the graphical distribution of moments. The moment diagram derived by graphical distribution offers a means of comparing the directions of moments and forces visually, and obviates the need for approximate sketching, such as that suggested by the author. Furthermore, graphic methods can be checked readily, simply by inspection.

For example, consider the frame in Fig. 31(a) in which the cross sections are constant. Basic stiffnesses, $\frac{I}{L}$, are shown in circles. The moments are determined graphically by the use of "three-line polygons" and "cross lines" (22) constructed at the "central points," points of inflection, and elastic points (see Fig. 31(b)) of each member.

FIG. 31.—GRAPHICAL SOLUTION BY SUPERPOSITION

When all members of the frame have uniform cross sections the "central points" are at the third points of the span, and the point of inflection is located by drawing line 1, Fig. 31(b), through the stiffness ordinate at the support and through the ordinate at the third point that marks one half the basic stiffness. The stiffness ordinate for each member is determined by drawing line 2, Fig. 31(b), through the point of inflection at the far end and through the ordinate at the third point that marks one half the basic stiffness of the span being analyzed. The point of inflection in the member with a fixed end is at the third point of the span. The elastic point for the intermediate joint B, Fig. 31(a), is determined by constructing a three-line polygon. Line 3, Fig. 31(b), is drawn through the intersection of line 2 with the vertical at the third point of the span and through the intersection of line 1 with the vertical at the third point in the adjacent span. The place where line 3, Fig. 31(*b*), intersects the axis of the member is the elastic point.

Moments due to the vertical force are determined graphically by "cross lines" (see Fig. 31(*a*)). When joint B is displaced a unit distance the resulting distortion diagram is as shown in Fig. 31(*d*); and the resulting moments in member AB, by the formula—

$$M_{AB} = \frac{600\, I\, a}{L^2_1\,(L_1 - a - b)} \dots\dots\dots\dots\dots\dots (86)$$

—are $M_{AB} = 29.6$ and $M_{BA} = 21.3$. In Eq. 86, a and b are the distances of the points of inflection from ends A and B, respectively. The numerical factor 600 is introduced for convenience of computation.

The manner of distributing the moments M_{AB} and M_{BA}, as well as the distortion moments for the other members of the frame, is indicated by the dotted lines in Fig. 31(*e*). The final moments are indicated by full lines. The moment diagram for member AB, showing also the direction of the moments and forces, is presented in Fig. 31(*c*) in a convenient form for memorizing.

By statics:

$$-\,2{,}812\,k = 200 \dots\dots\dots\dots\dots\dots (87)$$

in which $k = -\,0.071$. Eq. 87 is similar in form to Eq. 25. The final moments are equal to the algebraic sum of the moments in Fig. 31(*a*) and Fig. 31(*e*), multiplied by factor $k = -\,0.071$. As shown graphically in Fig. 31(*f*), these final moments differ slightly from those computed by the author.

The drawing can be included on a sheet the size of an ordinary business letter, although greater accuracy, where required, may be obtained by using a larger scale. The sidesway of members with haunches may be determined similarly, necessary constants being computed independently, or scaled (22) from diagrams.

To summarize: The author declared the purpose of his paper (see heading, "Synopsis") to be "to demonstrate the usefulness of the principle of superposition in the analysis of rigid frames by the slope-deflection and moment distribution methods." Granting the usefulness of the principle of superposition, it is the latter part of the foregoing statement which the writer questions. The writer's purpose has been to plead the virtue of more simple design procedures in demonstrating the acknowledged worth of the principle of superposition.

VICTOR R. BERGMAN,[15] ASSOC. M. AM. SOC. C. E.—For the analysis of those rigid frames in which the effect of joint translation as well as of joint rotation must be considered, Professor Wilson has presented a useful, interesting method of procedure involving superposition. Although some of the problems in this paper can be solved more readily by other approaches, all the examples have a definite value in developing and illustrating the method.

---

[15] Structural Designer, York and Sawyer, Architects, New York, N. Y.

One of the frames analyzed by Professor Wilson, the gable bent in Fig. 10, has enjoyed quite a vogue in technical literature. The author's treatment of this problem is instructive, and indicates the ease of application of the method to this type of structure, when the component members are of constant cross section. However, the growing demand for artistically pleasing structures leads to the construction of many of these frames with members of varying cross section. In this case, a gable bent often can be analyzed more advantageously by some other method such as column analogy.

It may be of value to point out that the "Relation Between Values of *R* for Members of a Quadrangle" (see subheading under "Nonrectangular Frames") can be determined readily by a semigraphical method. The gable bent in Fig. 10, redrawn in Fig. 32(*a*), will be used for purposes of illustration.

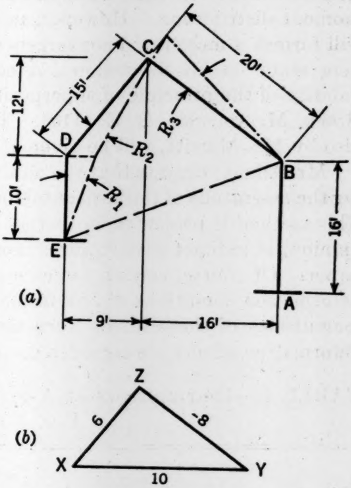

Fig. 32

In Fig. 32(*b*), using any convenient scale, lay off a length, XY, of 10 units at right angles to leg DE of the gable bent. Through points X and Y draw lines perpendicular, respectively, to members CB and CD, intersecting at point Z. The values of XZ and YZ are found, by scaling, to be 6 and 8 units, respectively. Then: $R_1 = \frac{10}{10} R_1 = R_1$; $R_2 = \frac{8}{15} R_1$; and $R_3 = \frac{6}{20} R_1 = \frac{3}{10} R_1$.

David M. Wilson,[16] M. Am. Soc. C. E.—Several of the discussions have concerned methods of balancing moments at the joints in step 3 of the paper. Messrs. Stewart and McGee prefer the traverse method (17) for this purpose, whereas Messrs. Polivka and Eremin use the graphical method of fixed points. Although these methods have definite limitations (17*a*) not possessed by the general slope-deflection and moment distribution methods, they will be found useful in the analysis of continuous beams and one-story frames. In this connection, a special technique in the use of slope deflection will be presented subsequently which accomplishes the same purpose as the traverse method.

Mr. Fischer presents some short cuts in the application of moment distribution to several of the simple examples of the paper. These are useful to the experienced designer in simplifying distribution calculations for many problems where they apply. In the paper, short cuts were intentionally avoided in order that the usefulness of superposition might be demonstrated without giving undue attention to distribution procedures. Furthermore, the slope-deflection and moment distribution methods, as used in the paper, are well known and perfectly general in their application to the analyses of all types of rigid frames.

---

[16] Prof., Civ. Eng., Univ. of Southern California, Los Angeles, Calif.

Mr. Merritt questions the validity of conclusion 4. The writer agrees with him that nearly all rigid-frame problems can be solved most expeditiously by moment distribution. However, in certain cases, slope-deflection procedures will furnish a more rapid convergence than moment distribution, as Mr. Goldberg states in his discussion. A comprehensive treatment of the limits of validity of the principle of superposition has been presented by J. A. Van den Broek, M. Am. Soc. C. E. (11*a*). The treatment of moving loads, suggested also by Mr. Merritt, will be given attention subsequently.

Mr. Albert suggests that the method of procedure is improved by determining the magnitude of the horizontal force required to prevent sidesway in Fig. 27. This method is presented in textbooks (3*b*) and elsewhere but, in the writer's opinion, is indirect and requires more computations than the method of the paper. Of course, certain forces must be assumed to act during the several deformation conditions of any frame; but it is not necessary to determine the magnitudes of these forces since they cancel each other when the resultant deformation effects are considered.

Mr. Hall presents an interesting and instructive discussion of the determination of the relative *R*-values for members of a quadrangle by reference to the instantaneous center of rotation. For the same purpose, Messrs. McGee and Bergman use a convenient semi-graphical method which is familiar to most structural analysts (3*c*). The question by Mr. Bergman concerning the analysis of frames having members of varying cross section is answered by Messrs. McGee and Blog and is given further consideration in this closure.

To clarify the general questions raised and problems suggested in the discussions, the following comments will deal with (*a*) the treatment of moving loads, and (*b*) the presentation of the general slope-deflection equation for members having varying moments of inertia in a form convenient for use in either the slope-deflection or moment distribution method of analysis. The part concerning moving loads will include the general solution by moment distribution and a special solution by slope deflection (applicable to continuous beams and one-story frames) which accomplishes the same purpose as the traverse method (17). The part dealing with varying moment of inertia will include a special solution by slope deflection, similar to that used for frames having members of constant section, of the frame analyzed by Mr. McGee.

Moving Loads.—In the solution of problems involving moving loads, it is recommended that the effect of an applied moment at each joint on all members of the frame be determined at the outset, either by moment distribution or by slope deflection. The resultant effects of different combinations of loads, both with and without sidesway, can then be determined readily by proportion and superposition without additional calculations involving the balancing of moments at the joints.

General Solution by Moment Distribution.—Example 2 of the paper has been selected to illustrate the foregoing procedure, using moment distribution. Table 4(*a*) shows the distribution of an applied moment of 1,000 ft-lb (assumed) at joint B (Fig. 2). Similarly, effects of applied moments of 1,000 ft-lb each at joints C and E are determined, and a summary of the results obtained is given in Table 5. From the values in Table 5 (called flexure factors by Mr. Stewart (17)), the distribution of a required balancing moment at any joint can be determined by simple proportion. The balancing moment may be either a numerical value, or a function of unknown displacements, as explained in the paper. After all joints are balanced, steps 4 and 5 give a solution for each critical position of the loads. If influence lines are desired, several solutions for varying positions of a unit load must be made.

TABLE 5.—EFFECTS OF A MOMENT OF 1,000 FT-LB APPLIED AT JOINTS B, C, AND E, FIG. 2. (CLOCKWISE)

Joint	MEMBER (SEE FIG. 2(*a*))									
	AB	BA	BC	CB	CD	CE	DC	EC	EF	FE
B	179	358	642	204	−77	−127	−38.5	−20	20	0
C	−38	−76	76	388	231	381	115	63	−63	0
E	13.5	27	−27	−141	−83	224	−41.5	704	296	0

Special Solution by Slope Deflection.—A special solution by slope deflection of continuous beams and one-story frames, which accomplishes the same purpose as the traverse method (17), is very useful. Example 2 of the paper also has been chosen to demonstrate this application of slope deflection.

For the purpose of determining the effects of an applied moment at any joint, the slope-deflection equation may be written conveniently in the following form, dropping the constant factor 2 E:

$$M\ (\text{near}) = K\left[2\,\theta\ (\text{near}) + \theta\ (\text{far})\right] \qquad (38)$$

In Fig. 33(*a*), it is first assumed that the rotation angle at joint F is equal to unity. By applying Eq. 88 successively to the several members of the frame, the following simple calculations are made. First assume $\theta_F = 1$; then:

$$M_{FE} = 1\,(2\,\theta_F + \theta_E) = 0; \quad \theta_E = -2$$
$$M_{EF} = 1\,(2\,\theta_E + \theta_F) = -4 + 1 = -3$$

$$M_{EC} = 2\,(2\,\theta_E + \theta_C) = 3; \quad \theta_C = 1.5 + 4 = 5.5$$
$$M_{CD} = 1\,(2\,\theta_C + 0) = 11$$
$$M_{CE} = 2\,(2\,\theta_C + \theta_E) = 2\,(11 - 2) = 18$$

$$M_{CB} = 2\,(2\,\theta_C + \theta_B) = 2\,(11 + \theta_B) = -29; \quad \theta_B = -14.5 - 11 = -25.5$$
$$M_{BC} = 2\,(2\,\theta_B + \theta_C) = 2\,(-51 + 5.5) = -91$$

$$M_{BA} = 1\,(2\,\theta_B + 0) = -51$$
$$M_{AB} = 1\,(0 + \theta_B) = -25.5$$

The moment values thus obtained are shown at the ends of the members in Fig. 33(*a*). It is obvious that an applied moment of −142 ft-lb at joint B will induce these moments throughout the frame.

Fig. 33

Similarly, if it is assumed that the rotation angle at joint B is equal to unity, the moment values shown in Fig. 33(*b*) are obtained. It will be noted that a moment of −142 ft-lb at joint F is required to produce unit rotation at joint B, whereas (see Fig. 33(*a*)) a moment of −142 ft-lb at joint B produces unit rotation at F. This is in agreement with Maxwell's law of reciprocity of displacement and constitutes a valuable check on the calculations.

From the moment values shown in Figs. 33(*a*) and 33(*b*), the effects of an applied moment at either joint C or joint E can be determined readily as shown in Figs. 33(*c*) and 33(*d*).

Varying Moment of Inertia.—In the paper, it was stated that the method of procedure therein described is general and can be applied with little additional labor to the analysis of frames having members of varying section after fixed-end moments, carry-over factors, and stiffness values have been evaluated. Mr. McGee has shown in an excellent manner the application of the method of procedure to a two-bay, saw-toothed structure with tapering members. Inasmuch as he used the traverse method in balancing moments at the joints, it is considered desirable to present the general slope-deflection equation for members having varying moments of inertia in a form convenient for use in either the slope-deflection or moment distribution method of analysis. Reference to Fig. 34 will assist in making clear the meaning of the symbols.

(*e*) SIMPLE BEAM $\frac{M}{I}$-DIAGRAM FOR $M_{BA} = 1$

FIG. 34.—TYPICAL $\frac{M}{I}$-DIAGRAMS

General Slope-Deflection Equations.—The general slope-deflection equations for members having varying moments of inertia may be written in the following form:

$$M_{AB} = S_A\,(\theta_A + c_A\,\theta_B) - S_A\,(1 + c_A)\,R + C_{AB} \quad \text{(89}a\text{)}$$

$$M_{BA} = S_B\,(\theta_B + c_B\,\theta_A) - S_B\,(1 + c_B)\,R + C_{BA} \quad \text{(89}b\text{)}$$

in which (see Fig. 34): S_A is the rotational stiffness at joint A with joint B fixed against rotation; S_B is the rotational stiffness at joint B with joint A fixed against rotation; c_A is the carry-over factor from joint A to joint B; and c_B is the carry-over factor from joint B to joint A. For members of constant section, $S_A = S_B = 4\,E\,K$ and $c_A = c_B = \frac{1}{2}$, which values, when substituted in Eqs. 89, yield the familiar form of Eqs. 2.

Stiffnesses—Far End Fixed.—The rotational stiffnesses are defined as follows:

$$S_A = \frac{E\,(l - x_2)}{a_1\,(x_1 - x_2)} = \frac{E\,I}{l}\,\frac{1 - v}{p\,(1 - u - v)} = \frac{E\,I}{l}\,\alpha \quad \text{(90}a\text{)}$$

$$S_B = \frac{E\,x_1}{a_2\,(x_1 - x_2)} = \frac{E\,I}{l}\,\frac{1 - u}{q\,(1 - u - v)} = \frac{E\,I}{l}\,\beta \quad \text{(90}b\text{)}$$

in which (21): $a_1 = \frac{p\,l}{I}$ = area of a simple-beam *M*-diagram for $M_{AB} = 1$ (assumed a positive quantity); $a_2 = \frac{q\,l}{I}$ = the area of a simple-beam *M*-diagram for $M_{BA} = 1$ (assumed a positive quantity); $x_1 = l - u\,l$ = the distance from the centroid of the $\frac{M}{I}$-diagram for M_{AB} to end B of the member; $x_2 = v\,l$ = the distance from the centroid of the $\frac{M}{I}$-diagram for M_{BA} to end B of the member; u and v are ratios introduced by Walter Ruppel, Assoc. M. Am. Soc. C. E. (21); and α and β are stiffness coefficients defined as follows:

$$\alpha = \frac{1 - v}{p\,(1 - u - v)} \qquad (91a)$$

and

$$\beta = \frac{1 - u}{q\,(1 - u - v)} \qquad (91b)$$

For members having constant section, $\alpha = \beta = 4$.

Carry-Over Factors.—The carry-over factors in Eqs. 89 are defined as follows:

$$c_A = \frac{x_2}{l - x_2} = \frac{v}{1 - v} \qquad (92a)$$

$$c_B = \frac{l - x_1}{x_1} = \frac{u}{1 - u} \qquad (92b)$$

Fixed-End Moments.—The fixed-end moments caused by transverse loads on the member AB are defined as follows:

$$C_{AB} = -\frac{F\,(\bar{x} - x_2)}{a_1\,(x_1 - x_2)} = -\frac{F\,(\bar{x} - v\,l)\,I}{p\,l^2\,(1 - u - v)} \qquad (93a)$$

$$C_{BA} = +\frac{F\,(x_1 - \bar{x})}{a_2\,(x_1 - x_2)} = +\frac{F\,(l - u\,l - \bar{x})\,I}{q\,l^2\,(1 - u - v)} \qquad (93b)$$

The fixed-end moments induced by angular displacement, R, are

$$M'_{AB} = -S_A\,(1 + c_A)\,R = -S_A\,(1 + c_A)\,\frac{\Delta}{l} \qquad (94a)$$

$$M'_{BA} = -S_B\,(1 + c_B)\,R = -S_B\,(1 + c_B)\,\frac{\Delta}{l} \qquad (94b)$$

It should be noted that I in the foregoing formulas for stiffnesses and fixed-end moments is the minimum moment of inertia of the member. A valuable check of the calculated values of stiffnesses and carry-over factors is given by the following relation:

$$S_A\,c_A = S_B\,c_B \qquad (95)$$

Special Slope-Deflection Equation.—If one end (say, end B) of the member is free to rotate so that $M_{BA} = 0$, the following special slope-deflection equation can be derived from Eqs. 89:

$$M_{AB} = S_A\,(1 - c_A\,c_B)\,\theta_A - S_A\,(1 - c_A\,c_B)\,R + H_{AB} \qquad (96)$$

in which H_{AB} = the fixed-end moment at end A caused by transverse loads on the member, with end B hinged—expressed as,

$$H_{AB} = C_{AB} - c_B\,C_{BA} \qquad (97)$$

From Eq. 96, it is obvious that the rotational stiffness at end A of the member is $(1 - c_A\,c_B)$ times the rotational stiffness at end A when end B is

fixed against rotation. Also, the fixed-end moment at end A, which is induced by angular displacement R, is equal to $-S_A\,(1 - c_A\,c_B)\,R$.

Six tables giving carry-over factors and stiffness coefficients, and also values of the factor $(1 - c_A\,c_B)$, for members having varying moment of inertia have been prepared from the tables compiled by Mr. Ruppel (21) and are given in Tables 6(*a*) to 6(*f*), inclusive.

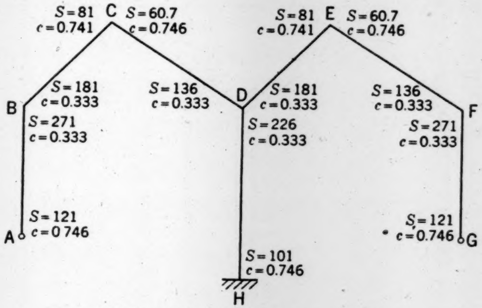

FIG. 35.—TWO-BAY, SAW-TOOTHED FRAME

Special Solution by Slope Deflection.—A special technique in the use of slope deflection, similar to that discussed previously herein for frames having members of constant section, will be applied to the frame analyzed by Mr. McGee. For the purpose of determining the effects of an applied moment at any joint of a one-story frame or continuous beam, the general slope-deflection equation for members having varying moments of inertia may be written conveniently in the following form:

$$M\,(\text{near}) = S\,(\text{near})\,[\theta\,(\text{near}) + c\,(\text{near})\,\theta\,(\text{far})] \qquad (98)$$

Fig. 35 represents the frame analyzed by Mr. McGee with relative values of the stiffnesses and values of the carry-over factors (taken from Table 6(*d*)) recorded at the ends of the appropriate members. It was first assumed that $\theta_G = 0.427$, in order to show the relation between the slope-deflection and traverse procedures (ordinarily θ_G would be assumed equal to unity).

By applying Eq. 98 successively to the several members of the frame, the following simple calculations are made. First assume $\theta_G = 0.427$; then:

$$\begin{aligned}
M_{GF} &= 121\,(0.427 + 0.746\,\theta_F) = 0; \quad \theta_F = -\,0.573 \\
M_{FG} &= 271\,[-\,0.573 + (0.333)\,(0.427)] = -\,117
\end{aligned}$$

$$\begin{aligned}
M_{FE} &= 136\,[-\,0.573 + 0.333\,\theta_E] = 117; \quad \theta_E = 4.30 \\
M_{EF} &= 60.7\,[4.30 + (0.746)\,(-\,0.573)] = 236
\end{aligned}$$

$$\begin{aligned}
M_{ED} &= 81\,[4.30 + 0.746\,\theta_D] = -\,236; \quad \theta_D = -\,9.66 \\
M_{DE} &= 181\,[-\,9.66 + (0.333)\,(4.30)] = -\,1{,}490
\end{aligned}$$

$$\begin{aligned}
M_{DH} &= 226\,[-9.66 - 0] = -\,2{,}180 \\
M_{HD} &= 101\,[0 + (0.746)\,(-\,9.66)] = -\,730
\end{aligned}$$

$$\begin{aligned}
M_{DC} &= 136\,[-9.66 + 0.333\,\theta_C] = 3{,}670; \quad \theta_C = 110 \\
M_{CD} &= 60.7\,[110 + (0.746)\,(-9.66)] = 6{,}240
\end{aligned}$$

$$\begin{aligned}
M_{CB} &= 81\,[110 + 0.746\,\theta_B] = -\,6{,}240; \quad \theta_B = -\,251 \\
M_{BC} &= 181\,[-\,251 + (0.333)\,(110)] = -\,38{,}700
\end{aligned}$$

$$\begin{aligned}
M_{AB} &= 121\,[\theta_A + (0.746)\,(-\,251)] = 0; \quad \theta_A = 187 \\
M_{BA} &= 271\,[-\,251 + (0.333)\,(187)] = -\,51{,}100
\end{aligned}$$

The foregoing moment values are shown at the ends of the members in Fig. 36(*a*). It is obvious that an applied moment of −89,800 ft-lb at joint B will induce these moments throughout the frame, and an angular rotation at joint G equal to 0.427 (which was assumed). It will be observed that the values of θ obtained in the foregoing solution check those in Fig. 21, and that the calculated moments are proportional to the values shown in the same figure.

FIG. 36.—EFFECTS OF APPLIED MOMENTS AT DIFFERENT JOINTS

Similarly, if one starts at joint B and assumes $\theta_B = 0.427$, the moment values shown in Fig. 36(*b*) are obtained. It will be observed that the moment at joint G required to produce this angular rotation is also equal to −89,800 ft-lb. This constitutes a valuable check on the computations, in agreement with Maxwell's law of reciprocity of displacement. From the moment values in Figs. 36(*a*) and 36(*b*), the effects of applied moments at joints C, D, E, and F can be determined easily in a manner exactly similar to that shown for frames having members of constant section (see Fig. 33).

Summary.—It has been demonstrated in the paper, and also in the discussions, that the principle of superposition is indispensable in the analysis of rigid frames by the slope-deflection and moment distribution methods where applied loads cause linear displacements of the joints.

As stated in the paper, the key to analysis in any case consists in the consideration of all possible conditions of deformation of the given frame. This initial step of the method of procedure, which is based upon the validity of superposition, is very important and cannot be overemphasized. The balancing of fixed-end moments at the joints by the general methods of slope deflection or moment distribution (or by special methods where they apply) is but one step in the solution of a rigid frame problem involving unknown linear displacements of the joints, as the outline of the method of procedure clearly shows. The principle of superposition, on the other hand, is applied constantly throughout the analysis and, therefore, is deserving of special emphasis.

EXPERIENCE IN LOS ANGELES, CALIF.

BY R. F. GOUDEY,[1] M. AM. SOC. C. E.

SYNOPSIS

Interesting research on the thickening of various types of sludge was conducted on a practical scale by the Bureau of Water Works and Supply of the City of Los Angeles at a 200,000 gal per day demonstration plant which operated continuously from May 12, 1930, to January 6, 1934.[2] The plant, treating a raw sewage averaging 388 ppm total suspended solids and 394 ppm biochemical oxygen demand, included units of preliminary sedimentation, activated sludge, final sedimentation, coagulation and filtration of various types of sludges, sludge digestion, coagulation and filtration of activated sludge effluent, sludge concentration, sludge digestion, and vacuum filtration of sludge. The plant was radically designed in that the aeration period was 3 hr and was radically operated in four respects: Dissolved oxygen was maintained in the settled activated sludge; aeration tank solids were maintained at 1,000 to 1,600 ppm; returned sludge was carried at 45% or less; and returned sludge was added at different stages in the aeration process.

INTRODUCTION

Several axioms regarding sludge volumes must be kept in mind: First, as percentage removals of sludge from plain settling tanks increase, so the percentage moisture in the sludge increases. Second, sewage solids passing preliminary clarifiers into aeration or chemical processes become quite liquid even up to 99.5%. This means that in a complete treatment plant the greater the percentage removal of sludge in the preliminary clarifier, the lower will be the total sludge volume. Third, sludge-bulking characteristics apply not only to activated sludge, but to fresh and digested sludge as well. Fourth, washing sludge in clarifiers from storm flows or clear night flow or diluting sludges with fresh water (which practices have been recognized and used even prior to 1930) tend to produce denser sludges.

SLUDGE BULKING

Bulking of sludge is a phenomenon not restricted solely to activated sludge. For a given sewage, the fresh sludge moisture content increases with the percentage removal of total solids. Fresh sludge itself may be bulked from pH-variations above and below neutral, entrained carbon dioxide, carbonates, pectin, comminuted organic wastes of light specific gravity, and filamentous organic growths. Automatic pH-control, with lime, aids in producing fresh sludge with a low moisture content. Washing with water, whether from dilute sewage at low flow, storm water, or water added for elutriation, likewise aids.

[2] "Sewage Reclamation Plant for Los Angeles," by R. F. Goudey, *Western Construction News*, October 25, 1930, p. 519.

Mechanical mixing in the bottom of clarifiers or by mixing paddles for mechanical flocculation may assist in producing superior fresh sludges.

Bulking of activated sludge may be caused by many physical conditions similar to those for the bulking of fresh sludge. The process of "bulking" is not fundamentally biological because activated sludge can be bulked instantaneously by physical means long before bacteria or fungi could possibly multiply to account for it biologically.[3] Many organic and inorganic compounds that are laxative to man appear to be capable of bulking activated sludge. Pulp of fresh or dried apricots, figs, and tomatoes aerated in water become suspended in a relatively large volume. Onion and similar pulps, first alkalized and then made neutral, will also cause distended and bulky suspensions. When small amounts of activated sludge are added to pure pulp suspensions, the sludge becomes distributed throughout the pulp suspension and appears "bulked." A little activated sludge in a suspension of pure magnesium hydroxide appears enormous. In all these cases the activated sludge is distended and dispersed. Granite dust, sand, lime, or dilution with water, in all these cases, can reduce the "bulk" from 95% to 30% almost instantaneously, just as an increase in the pH-value in the magnesium hydroxide floc causes its immediate concentration. Lime is probably effective also in destroying enzymes, inverting colloidal phases, and in releasing ammonia.

Any sequence of treatment that controls bulking in all types of sludges and removes as large a part, as is practical, of the sewage solids as fresh sludge constitutes the first fundamental step in sludge concentration. The solids in passing preliminary clarifiers into aeration or chemical treatment units are converted into extremely liquid sludges, 97% to 99.5%, which constitute the main problem so far as concentration is concerned.

Excess Activated Sludge.—Three methods of excess activated sludge concentration were investigated by many months of practical and continuous operation. The first procedure was concentration by filling a tank with excess activated sludge, allowing it to settle by batch treatment for 24 hr, withdrawing water from clear zones between sludge and scum, and finally pumping the remaining sludge, which averaged 97.76% water. The second method was the return of excess activated sludge continuously to the preliminary clarifier which raised the moisture in the fresh sludge from 91.96% to 94.42%.

The third method consisted of continuous removal of excess sludge as equivalent aeration tank liquor, settling it at a rate of 600 gal per sq ft per day in a separate clarifier and treating the supernatant liquor to maintain a chlorine dose of 1 ppm over the settled sludge. The chlorine dose was equivalent to 20 lb per million gallons of sewage treated. The chlorine in the waste overflow was used to disinfect the final effluent from the entire plant.

No scum appeared on the thickening tank. Sludge was pumped once daily. This procedure produced an average moisture content of 94%. Washing with water produced sludges as low as 92%. The addition of lime averaged a sludge moisture of 90%. The addition of such inert materials as ground oyster shell, decomposed granite, and magnesite produced concentrated activated sludges as low as 76%.

---

[3] "Demonstration on Bulking and Debulking of Activated Sludge at Escondido Plant," by R. F. Goudey, *California Sewage Works Journal*, Vol. V, No. 1, 1932-33, p. 61.

Excess activated sludge in Southern California can be reduced, readily and economically, to a moisture content of 92%, although a limit of 94% is sufficient where the sludge is pumped to digesters. The main secrets are: First, the settling of thin sludge from aeration tanks carrying 1,000 to 1,500 ppm of solids instead of settled sludge from the activated sludge clarifiers; second, settling at the rate of 600 gal per sq ft per day; third, the addition of chlorine of 1 ppm to prevent scum formation and to cause thickening; and, fourth, use of a continuous operating basis. If re-aeration tank liquor or settled activated sludge from the secondary clarifier is used, a smaller concentrating tank is required but the moisture contents will range from 96% to 97%.

In order to visualize the relative value of the foregoing four methods, a tabulation of the resultant combined volumes of fresh and activated sludges for a plant producing one ton of dried fresh solids at a moisture content of 91.96%, and two tons of dried excess activated sludge at 99.8% moisture, is as shown in Table 1.

TABLE 1.—COMBINED VOLUME OF WET, FRESH AND THICKENED ACTIVATED SLUDGE FOR VARIOUS METHODS OF CONCENTRATION

No.	Process	Moisture content (%)	Combined volume (gal)
1	Settled activated sludge mixed with fresh sludge	97.76	24,100
2	Excess sludge pumped to clarifier	94.42	12,900
3	Aeration-liquor settled under chlorine and mixed with fresh sludge	92.00	9,000
4	Aeration liquor settled under chlorine and mixed with fresh and activated sludge	90.00	7,200

The City of Phoenix, Ariz., installed a sludge thickening tank[4] for both fresh and excess activated sludge. Dario Travaini, Assoc. M. Am. Soc. C. E., reports that fresh sludge has been reduced to 85% moisture but not without troublesome odors. The fresh sludge has an average moisture content of 95% and the excess activated sludge averages 97.4% moisture. These high values are due to chemical treatment prior to preliminary clarification and also to the fact that the thickening plant is too small to use aeration tank liquor rather than activated sludge itself. Mr. Travaini also reports that the Phoenix plant has "never successfully concentrated activated sludge in the primary clarifier" and that the digesters would "fail completely" if it were not for the sludge concentration tank employing chlorine.

It is apparent that the chlorine settling method is superior to that of pumping excess activated sludge to the preliminary clarifier where good removals are required and where digestion is involved. In case the final effluent needs to be chlorinated, the chlorine serves both for sludge concentration and mixture of the sludge liquor carrying sufficient chlorine to disinfect the final effluent. For moderate removals and where chlorination of the final effluent is concerned, concentration of activated sludge need not be carried below 94%.

---

[4] "Sludge Thickening at Phoenix, Arizona," by Dario Travaini, *Water Works and Sewerage*, April 1934, p. 107.

Digested Sludge.—As early as 1930 successful experimental runs were conducted on digested sludge treated with various quantities of ferric chloride and lime followed by vacuum filtration. The average dose was 4% ferric chloride and 10% lime. Digested sludge produced a cake of 65% moisture content at a chemical and filtration cost of \$3.50 per million gallons.[5]

Raw Sludge.—It was found that chemical doses calculated on the basis of dry solids used to concentrate digested sludge likewise concentrated fresh sludge; and this procedure permitted equally satisfactory dewatering of fresh sludge for either vacuum filtration or rapid sand bed drying. This indicates that digestion is an unnecessary step where chemical treatment of sludge is justified for other reasons.

CONCLUSIONS

All practices that will produce a concentrated sludge—whether fresh, activated, or digested—should be given due consideration. The cheapest way to remove solids of lowest moisture content is in the first clarifier where attention is paid to pH-control of the incoming sewage, mechanical flocculation, timing of sludge removal, and washing and dilution of sludge.

Excess activated sludge can be concentrated best by removing its equivalent as aeration tank liquor, diluted with water to 1,200 ppm and treated with lime occasionally, followed by sedimentation under a 1 ppm chlorine blanket. The withdrawal of aeration tank liquor should be continuous, the settling tank need never be emptied, and the thickened sludge should be pumped not more frequently than once a day. By this procedure, moisture contents of 94% can be attained.

When it comes to producing sludges of maximum concentration, digestion is unnecessary and wasteful. The economy of sludge concentration is based fundamentally on the degree of solids to be removed by a given plant, whether the final effluent needs chlorination, and whether vacuum filtration of sludge is required.

BACK RIVER SEWAGE WORKS, BALTIMORE, MD.

By C. E. Keefer,[6] M. Am. Soc. C. E.

Synopsis

When the preliminary plans for the additions to the Back River sewage works in Baltimore, Md., consisting of activated-sludge units, were made in 1937, it was decided to provide tanks for the thickening of the excess activated sludge. These tanks have been in almost continuous service since they were put in operation on November 27, 1939, and have given satisfactory service.

Description of Thickening Tanks

Two thickening tanks were constructed, each 26 ft in diameter with a working depth of 16 ft. The excess sludge enters the tanks through a vertical central column, and the supernatant flows radially outward and discharges over a V-notched weir at the tank periphery. A mechanism is supported by and rotates about the aforementioned column at a speed of one revolution in 14.75 min. The bottom of the mechanism is provided with squeegees for moving the settled sludge along the tank floor to the sludge discharge pipe near the center of the tank. Vertical steel angles, for thickening the sludge, are also attached to the mechanism. Projecting vertically downward 12 in. below the surface of the supernatant in each tank are 8-in. nozzles through which chlorine water can be discharged.

The two tanks were designed to thicken the excess sludge when the sewage flow treated by the activated-sludge units would amount to 40 mgd. It was estimated that 160,000 gal of excess sludge, containing 1.5% of dry solids, would result from treating the aforementioned quantity of sewage. With this flow of sludge the surface loading, with one thickening tank in service, would be 300 gal per sq ft daily. A total of 13 ft was allowed for deposited sludge and 3 ft for supernatant in the tanks. The supernatant from the tanks is pumped into the settled sewage being treated by the activated-sludge units, and the thickened sludge flows to two plunger pumps. These pumps discharge the material through a 6-in. cast-iron force main into a well, which receives the raw sludge from the preliminary sedimentation tanks. The mixture of raw primary and activated sludges is then pumped into heated digestion tanks.

This treatment of the activated sludge indicates the reasons for thickening it, namely:

1. To reduce pumping costs;
2. To save fuel for heating the sludge; and
3. To reduce the volume of space in digestion tanks occupied by water.

---

[6] Associate Engr., Bureau of Sewers, Baltimore, Md.

OPERATING RESULTS

When the thickening tanks were designed, it was expected that each tank would treat the excess sludge resulting from the treatment of 20 mgd of sewage. Operating experience has indicated the desirability of frequently using two tanks even when the sewage flow is less than 20 mgd. Item 5, Table 2, indicates that during the 3-yr operating period from 1940 to 1942, inclusive, two tanks were in service from 59% to 64% of the time. When the sludge index is low one tank is sufficient to thicken the sludge, but when the index begins to increase materially two tanks are necessary.

TABLE 2.—OPERATING RESULTS AND DATA, ACTIVATED-SLUDGE THICKENING TANKS, BALTIMORE, MD.

No.	Description	1940	1941	1942
1	Quantity of sewage treated (mgd)	15.61	13.28	11.94
	Depth of Sludge in Tanks (Ft):			
2	From	7.7	4.9	9.1
3	To	14.0	11.7	
	Percentage of Time in Service:			
4	One tank	36	39	41
5	Two tanks	64	61	59
	Sludge to Thickener:			
6	Quantity (gal per million gal of sewage)	46,000	22,520	18,000
7	Solids (%)	0.9	1.1	0.9
8	Volatile matter (percentage dry weight)	77.1	79.5	80.1
	Sludge from Thickener:			
9	Quantity (gal per million gal of sewage)	5,370	4,231	4,500
10	Solids (%)	1.9	2.1	1.4
	Thickener Effluent (PPM):			
11	Five-day biochemical oxygen demand	88	....	....
12	Suspended solids	96	81	197
13	Chlorine applied to unthickened sludge (ppm)	16.5	29.4	10.0
14	Reduction in volume of sludge (%)	88.3	81.3	75.0

The performance of the thickening tanks from 1940 to 1942, inclusive, is indicated by Items 6 to 14 in Table 2. The reduction in the volume of the sludge (Item 14) has varied from 75% to 88.3%, with an increase in solids of from 0.9% or 1.1% (Item 7, Table 2) to 1.4% or 2.1% (Item 10, Table 2). The effluent from the thickeners (Item 11) had an average 5-day B.O.D. of 88 ppm in 1940 and an average yearly suspended solid content (Item 12) varying from 81 to 197 ppm. The chlorine applied to the unthickened sludge varied from 10.0 to 29.4 ppm (Item 13, Table 2).

A marked correlation was observed between the sludge index and the solids, in the unthickened and the thickened sludge (Fig. 1(*a*)). When the sludge index was low, the solid content in the unthickened and the thickened sludge was high; and, when the sludge index was high, the reverse condition was observed. The ratio of the solids in the thickened and the unthickened sludge (R) was also found to vary inversely with the sludge index (Fig. 1(*b*)). This relationship can be expressed by the formula

$$R = 7.94\, s^{-0.3125} \qquad (1)$$

in which s is the sludge index. Eq. 1 is based on three years of operating results, and may require modification when more operating data are available. It is not intended to apply to other than Baltimore conditions. No correlation was found between the amount of inorganic matter in the sludge and the solid content and the sludge index, perhaps because there was insufficient variation in the amount of inorganic matter in the sludge.

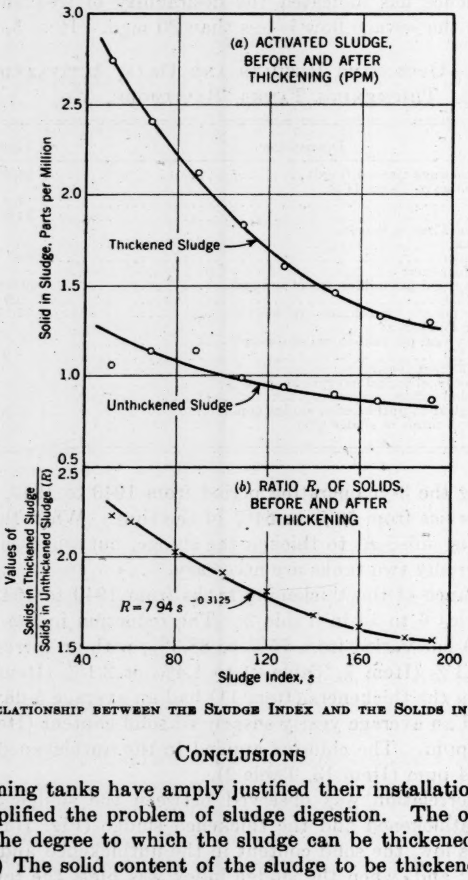

FIG. 1.—RELATIONSHIP BETWEEN THE SLUDGE INDEX AND THE SOLIDS IN THE SLUDGE

CONCLUSIONS

The thickening tanks have amply justified their installation, as they have materially simplified the problem of sludge digestion. The operating results indicate that the degree to which the sludge can be thickened depends upon two things: (1) The solid content of the sludge to be thickened; and (2) the sludge index of the unthickened sludge.

ACKNOWLEDGMENTS

The activated-sludge units were designed by the firm of Whitman, Requardt and Smith, consulting engineers. The Back River sewage works is under the general supervision of Nathan L. Smith, M. Am. Soc. C. E., chief engineer, Department of Public Works, and George E. Finck, M. Am. Soc. C. E., sewerage engineer.

SOME RESULTS IN THE STATE OF NEW JERSEY

BY WILLEM RUDOLFS,[7] M. AM. SOC. C. E.

SYNOPSIS

The purpose of sludge concentration or sludge compaction is primarily to reduce the bulk of the sludge and subsequently to effect economy in handling. The method of sludge concentration may be physical, chemical, or both. The ultimate sludge concentration obtained is affected by various factors, chiefly the character of the sludge, its initial concentration, time of compaction, temperature, and pressure. If chemicals are used, the type of chemical is important.

This paper is in the nature of a résumé and deals with several of these factors. The results reported are based upon laboratory and plant scale studies.

The character of the sludge to be concentrated is of greatest general importance. The effects of initial concentration, time of compaction, and temperature during concentration, as well as the effect of the chemicals used, vary for different types of sludges.

The studies on which this paper is based have been made on the three major types of sludges (fresh solids, digested sludges, and waste activated sludges). Because of the mass of data, only some of the results are discussed under separate headings.

FRESH SOLIDS

Initial Concentration.—The reduction in volume of sludge when it is quiescent is naturally greatest with the lowest initial concentration. As an illustration, fresh solids, allowed to compact for 120 hr at a winter temperature of 50° F, with initial concentrations of from 0.5% to 6.2%, show decreasing rates of compaction with increasing initial concentration (Fig. 2). The compaction is greatest during the first 24 hr.

Effect of Time.—Table 3 shows the effect of time on the concentration of fresh solids under actual plant conditions obtained at the Rahway Valley (New Jersey) Sewage Treatment Plant over a period of 3 yr. The average monthly results, irrespective of temperature effects, are shown in Fig. 3. The results confirm closely the laboratory results obtained with fresh solids from the same source as that shown in Fig. 2. Concentration is very rapid during the first 12 hr, followed by a gradual reduction in the rate of compaction.

TABLE 3.—MONTHLY AVERAGE, FRESH SOLIDS CONCENTRATION

Hours of concentration	PERCENTAGE OF TOTAL SOLIDS		
	Minimum	Maximum	Average
12 to 18	3.80	6.90	5.57
24	5.30	8.30	6.42
36 to 48	6.4	8.30	7.19

Effect of Temperature.—Experiments and observations made at the Elizabeth (N. J.) Joint Meeting Sewage Treatment Plant, where the fresh solids are concentrated in tanks prior to barging to sea, show that concentration of solids is materially greater in summer than in winter. As an illustration, Fig. 4 compares the concentration of fresh solids kept at winter temperatures (47° F to 50° F), with similar solids concentration at summer temperatures (75° F to 80° F). The initial total solids concentration of 5.2% increased during 96 hr to 11.5% in summer as compared with 8.7% in winter. Practice for several years has shown that the sludge volume is materially less in summer than in winter, but handling the less concentrated sludge in winter is more difficult than handling the denser sludge produced in summer. The reason is primarily a question of viscosity of the sludge, which is appreciably greater in winter.[8]

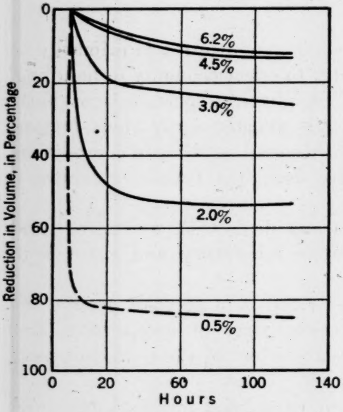

FIG. 2.—RELATION BETWEEN TIME OF COMPACTION AND REDUCTION IN SLUDGE VOLUME

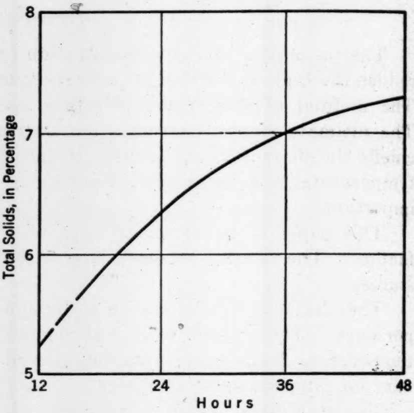

FIG. 3.—AVERAGE RESULTS OBTAINED ON PLANT SCALE DURING THREE YEARS

The effect of sludge concentration on cost of operation may be illustrated by the volumes of sludge collected and the percentage reduction in volume obtained during 1940, 1941, and 1942. The sludge pumped in 1940 was 70,700 gal per day, which increased to 74,378 gal per day in 1941. On account of increased solids concentration, however, the reduction in volume amounted to 42.4% in 1941 as compared with 36.1% in 1940, so that less sludge had to be barged in 1941 than in 1940. During 1942 the sewage flow increased, and subsequently the sludge quantity increased to an average daily amount of 91,673 gal, or an increase in volume of 17%. Improved procedures in decanting led to increased solids concentration, reaching an average for the year of 8.14% total solids, so that only 83,000 tons, or about half of the increased quantity of sludge, needed barging.

---

[8] "Properties of Sludge Which Affect Its Discharge Through 24-In. Pipe," by Willem Rudolfs and Leslie E. West, *Sewage Works Journal*, Vol. XII, 1940, p. 60.

Effect of Temperature on Pumping Time.—The concentrated sludge is barged to sea at approximately two-week intervals. The sludge is pumped through a 24-in. line about 4,000 ft long. The time required for pumping is an expensive item in the disposal of the sludge. The temperature of the sludge has a substantial effect on this time (see Table 4). During 1942 the pumping time amounted to 70 min per 1,000 tons of sludge with sludge temperatures of from 68° F to 73° F, in contrast to 120 min per 1,000 tons of sludge at temperatures of from 51° F to 57° F. Thus, about 80% more time was required during the winter period.

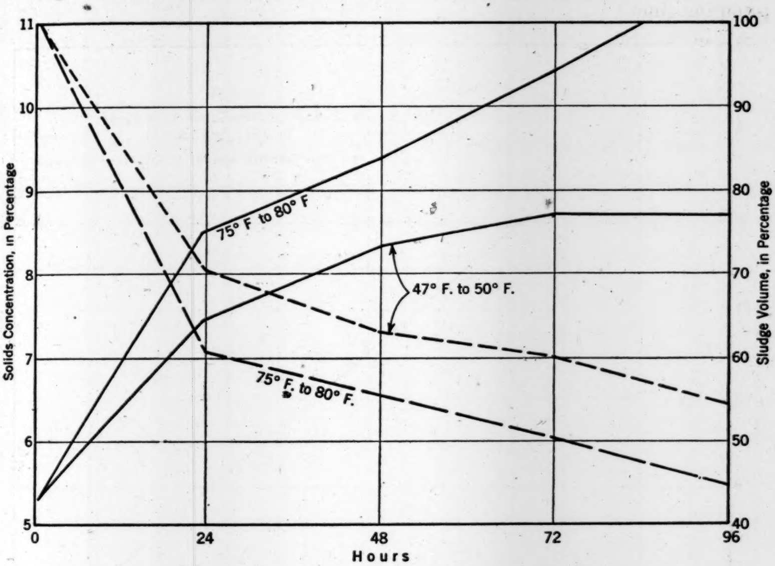

FIG. 4.—SUMMER AND WINTER TEMPERATURES AFFECTING CONCENTRATION OF FRESH SOLIDS

TABLE 4.—RELATION BETWEEN TEMPERATURE OF SLUDGE AND PUMPING TIME, 1942

(Elizabeth Joint Meeting Sewage Treatment Plant)

Number of bargings	Temperature range (degrees F)	Total solids (%)	Ash (%)	Tons barged	Average pumping time per 1,000 tons (min)	Average temperature (degrees F)
24	51–73	8.14	25.3	76,070	92	63.5
8	51–57	7.91	22.4	23,870	120	53.5
6	62–66	8.38	28.2	19,145	90	64.5
10	68–73	8.28	29.1	33,055	70	70.7

Plotting the 3-yr averages of individual temperatures prevalent during bargings clearly shows the relationship between temperature and time (see

Fig. 5). These results were actually obtained, and the curve cannot be drawn further without data to cover the extension. With the decreasing sludge temperatures the viscosity of the sludge increases, resulting in increased pumping time.[8]

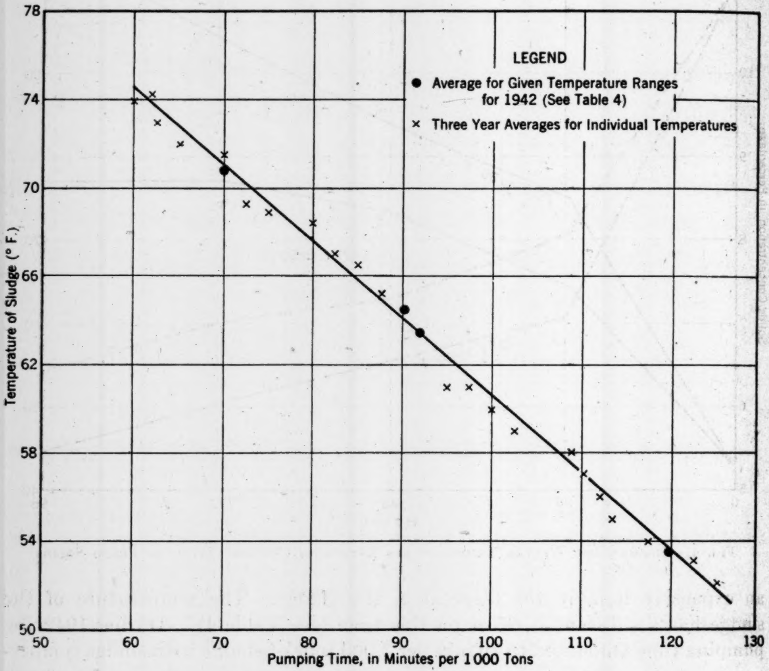

FIG. 5.—RELATION BETWEEN TEMPERATURE OF SLUDGE AND PUMPING TIME OBSERVED UNDER ACTUAL OPERATION

DIGESTED SLUDGE

The primary factors affecting fresh solids concentration—namely, initial concentration, time, and temperature—also affect concentration of digested sludge.

Initial Concentration.—The percentage reduction in volume decreases with increasing initial concentration. Compaction of ripe sludge proceeds in a manner similar to that of fresh solids, but the final solids concentration that can be obtained is greater. However, the fresh solids are more gelatinous in nature than the ripe sludge and they hold water more tenaciously, resulting in less dense sludge.[9]

Effect of Time.—The effect of time on ripe sludge compaction is similar to that on fresh solids. However, with initial higher solids contents, the concentration of ripe sludge is more rapid than similar concentration of fresh solids with equal elapsed time. For instance, with an initial concentration of 5%, fresh solids may be expected to concentrate 15% in 48 hr on an average, whereas ripe sludge increases under the same conditions an average of 30%. The percentage concentration varies with the length of time allowed for concentration.[10]

---

[9] "Sludge Compacting," by Willem Rudolfs and Robert P. Logan, *Sewage Works Engineering and Municipal Sanitation*, Vol. 14, 1943, p. 10.

Effect of Temperature.—The effect of temperature is less on ripe sludge than on fresh solids. As an illustration, results obtained with ripe sludges of different initial concentrations allowed to compact at summer and winter temperatures are shown in Fig. 6(*a*). The curves indicate that, with an initial concentration of 5% solids, a decrease in volume of about 50% can be expected after 72 hr of compaction. The difference in compaction during summer and winter is very small as compared with differences in fresh solids concentration (see Fig. 6(*b*)). The greater difference in fresh solids compaction is due mainly to the slimy character of the material and the gases produced during the initial stages of decomposition. The acidic compounds formed during decomposition, together with the gas produced, cause the fresh solids to float whereas the ripe sludge compacts at the bottom of the container or tank used.

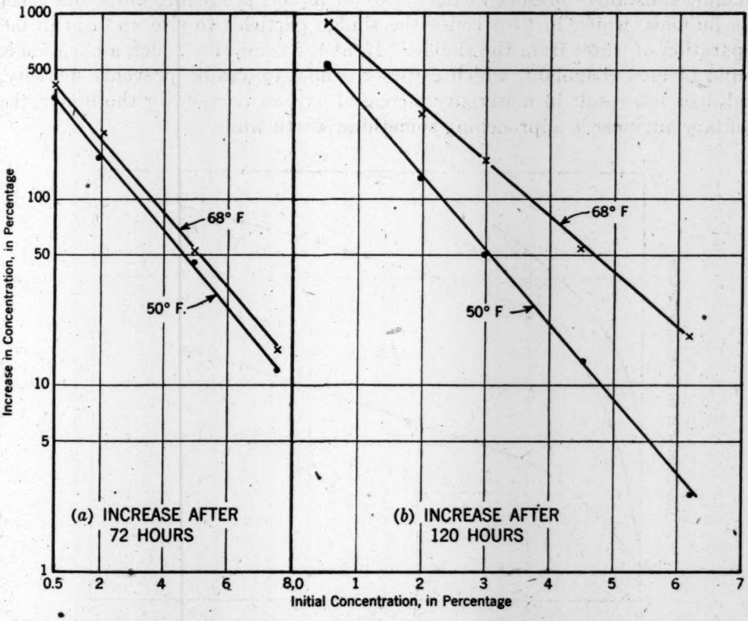

FIG. 6.—EFFECT OF WINTER AND SUMMER TEMPERATURES ON COMPACTION OF DIGESTED SLUDGE

---

[10] "Effect of Temperature on Sludge Concentration," by Willem Rudolfs and R. P. Logan, *Sewage Works Journal*, Vol. XV, 1943, p. 894.

ACTIVATED SLUDGE

Activated-sludge compaction is subject to the same factors that influence fresh solids and ripe sludge. Material along these lines has been published previously.[11] For that reason, some results obtained with certain chemicals to induce concentration of activated sludge are presented.

Experiments conducted over several years on the compaction of activated sludge produced: Large flocs, small flocs, flotation, dehydration, weighting, retardation of decomposition, and the combination of these methods with the aid of chemicals, inert materials, poisons, and gases.[12]

From the mass of results obtained, some dealing with induced flotation are selected. A flotation process with the aid of chemicals for dewatering of sludge has been used for a number of years. The acid chemicals react with the alkaline substances present in the sludge or liquor, producing numerous small gas bubbles, which in turn cause the sludge particles to rise and aid in the separation of water from the sludge. If, at the same time, such a chemical is found to be a coagulant, which causes the flocs to shrink, prevents septicity, and does not result in materially increased oxygen demand of the liquor, the sanitary engineer is approaching something worth while.

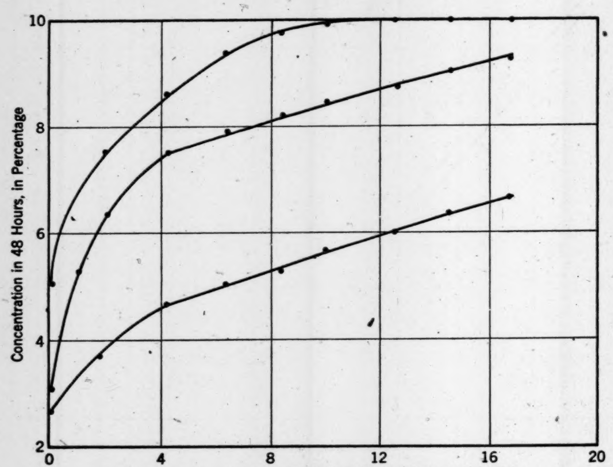

FIG. 7.—CHARACTER OF ACTIVATED SLUDGE IN RESPECT TO THE DEGREE OF OXIDATION

Results obtained with calcium hypochloride indicate that a dense, activated sludge may be obtained by flotation (Fig. 7). The concentration of the original waste, activated sludge (0.30% to 0.60%) does not appear to be a factor, but the character of activated sludge in respect to the degree of oxidation and the size of the floc seems to play a part. The 9% to 10% sludges produced by flotation are leathery in appearance, forming compact, cakelike sludges. The gases produced, which cause flotation, evolve freely when the sludge "cakes" are forming, but the sludge continues to compact materially after the first 24 hr. The chemical need not be added immediately upon discharge of the sludge. Letting the sludge stand for 10 hr at summer temperature and then adding the chemical produced the same sludge density after a total of 48 hr as that produced when the chemical was added at the beginning of the period. Allowing the sludge to become septic likewise had no effect. Neither age nor preliminary compaction, therefore, is detrimental or beneficial.

---

[11] "Concentration and Distribution of Sewage Solids During Digestion," by Willem Rudolfs and I. O. Lacy, *Sewage Works Journal*, Vol. III, 1931, p. 64.

[12] "Concentration of Activated Sludge by Compacting and Flotation," by Willem Rudolfs, *ibid.*, Vol. XV, 1943, p. 642.

It is well known that excessive quantities of chlorine added to activated sludge cause a dispersion or have a peptizing action on the sludge. The same reaction occurs with the addition of calcium hypochloride, but to a lesser extent. The biochemical oxygen demand (B.O.D.) of the liquor increases, but the highest value recorded, with quantities of calcium hypochloride three to four times greater than required, was 600 ppm. The liquor can be readily clarified by additions of small quantities of ferric chloride (0.4 lb per 1,000 gal), ferric sulfate, or chlorinated copperas, resulting in a clear liquor with a B.O.D. of about 100 ppm. The iron salt can be added at the same time as the calcium hypochloride. The addition of about 2 lb of sulfuric acid with the calcium hypochloride produces the same result.

The drainability of compacted sludge is enhanced by the calcium hypochloride treatment. The sludge drains readily, forming a thin, dry sheet, without the production of odors on standing. Sludge treated by calcium hypochloride is not improved by vacuum filtration.

SUMMARY

Sludge compaction is affected by the type and character of the sludge, initial concentration, time, temperature, and pressure. If chemicals are used, the type of chemical is important.

Sludges may be concentrated by settling and compaction or by flotation and compaction. Temperature is an important influence on the thickening rate of sludge. The method of compaction to be used depends upon subsequent disposal of the sludge. For barging and incineration, flotation processes appear feasible and may be more economical than compaction by settling.

CONCENTRATION OF SEWAGE SLUDGES, NEW YORK, N. Y.

By Wellington Donaldson,[13] M. Am. Soc. C. E.

Synopsis

Operating experiences and operating data for the sewage treatment plants of New York City are presented in this paper.

Some of the reasons for wishing to concentrate sewage sludges are quite obvious. For instance, in the case of heated digester tanks, it is desirable to introduce the sludge into the digester in well-concentrated condition, to avoid chilling the digesters by unnecessary quantities of cool liquor and at the same time to avoid the necessity of decanting from the digesters an equal quantity of heated supernatant liquor. Likewise, in connection with artificial dewatering and drying processes, it is advantageous to secure initial concentration of sludge. Where the liquid sludge is transported some distance from the plant for disposal, as is the situation locally, concentration is of considerable economic importance.

The density of sludge from primary tanks up to some 10% solids is largely controllable by the operator, depending upon the sludge pumping schedule and method of operating sludge collecting mechanisms. As a matter of fact, difficulties with collector mechanism, pump, or sludge piping from too dense a primary sludge may discourage maximum concentration. Few operators of activated sludge plants will agree that a comparable consistent and dependable control of the density of activated sludge exists. In fact, the difficulty of consistently concentrating activated sludge is the principal demerit to an otherwise very fine process.

In reviewing briefly the experiences of the more important sewage treatment plants of New York City, attention is directed to Table 5, showing the quality of the various sewage sludges.

Coney Island

The Coney Island plant, which, in May, 1942, was increased in capacity from 35 mgd to 70 mgd, employs plain sedimentation for eight months and chemical precipitation and chlorination during the four summer recreational months. All sludge is digested, and the liquid digested sludge is ordinarily transported by scow to natural sand beds or lagoons remote from the plant. There is little significance in the sludge data shown in lines 1 and 2, Table 5, since no particular effort was made to concentrate the raw or digested sludge beyond following a convenient operating schedule.

During the summer months when a ferric salt was used to aid sedimentation, the primary sludge ran about 8.5% solids as compared with the average value of 7.80% shown in Table 5. Because the digested sludge from this plant is transported by scow to beds or lagoons on Marine Park, it is advantageous to keep digested sludge reasonably dense. However, the 7.71% solids shown for the digested sludge is governed more by the running schedule of the sludge scows than by any manipulation within the plant.

[13] Chf., Bureau of Sewage Disposal Design, Dept. of Public Works, New York, N. Y.

TABLE 5.—AVERAGE QUALITY OF SEWAGE SLUDGES, NEW YORK CITY

No.	Description	Solids (%)	Volatile (%)
	(*a*) CONEY ISLAND PLANT		
1	Primary; 1941	7.80	63.1
2	Digested	7.71	49.0
	(*b*) WARDS ISLAND PLANT		
3	Primary; 1941	6.33	74.0
4	Aeration tank effluent	0.176	....
5	Returned sludge	0.48	....
6	Thickened activated sludge to storage	2.28	76.2
7	Weighted average, sludge to storage, primary to excess activated	4.30	....
8	Combined raw sludges to sea	4.45	74.6
	(*c*) BOWERY BAY PLANT		
9	Primary; 1941	7.10	68.2
10	Primary; 1942 (eight months)	5.38	62.9
11	Aeration effluent; 1942 (eight months)	0.16	....
12	Returned sludge; 1942 (eight months)	0.40	....
13	Thickened excess activated sludge; 1942 (eight months)	2.40	69.5
14	Combined raw sludges to digesters	4.03	....
	(*d*) TALLMANS ISLAND PLANT		
15	Primary; 1941 (January to May)	5.41	64.8
16	Primary; 1941 (June to December)	7.52	56.6
17	Aeration tank effluent (seven months)	0.152	....
18	Returned sludge (seven months)	0.51	....
19	Thickened activated sludge (five months)	1.35	56.5
20	Thickened activated sludge (seven months)	3.48	61.0
21	Combined raw sludges to digesters	6.41	....
22	Digested sludge to storage tank (twelve months)	5.94	....
23	Digested sludge to disposal (twelve months)	7.23	39.4

The wooden scows used for transporting the digested sludge from the plant to Marine Park are owned by the city. Towing is by contract, but the city personnel operate the gasoline driven pump on the scow for discharging the sludge through pipe and hose to the beds. Therefore, unnecessary scow trips would involve additional charges for towing, gasoline, and maintenance. During 1941 the disposal of digested sludge in this manner cost $4.31 per ton of dry solids delivered, capital charges included.

WARDS ISLAND

The Wards Island activated-sludge plant treats about 200 mgd of sewage. Both primary and excess activated raw sludge are finally disposed of by barging to sea in special Diesel-propelled sludge vessels, a distance of 34 miles from the plant. Therefore, it is of considerable importance that the sludge barged to sea be concentrated as much as possible. The primary settling tanks have retention periods of less than 1 hr. This probably limits the concentration of solids pumped from these tanks to the average of 6.33% solids shown in line 3, Table 5. Little can be done to change the density of the primary sludge, but the excess activated sludge requires continued watchfulness to avoid barging unnecessary water to sea. At this plant certain of the final settling tanks are set aside as sludge thickening tanks and operated at a slower rate to give a greater density of sludge than results in the regular final tanks. It will be noted from Table 5 that the return sludge averaged 0.48% solids (suspended solids, 4,800 ppm), whereas the thickened excess sludge from the special tanks averaged 2.28% solids. The computed weighted average of the combined primary and excess activated sludge was 4.30% solids. The difference between this and the succeeding value (4.45) represents a slight concentration secured in the sludge storage tanks by decantation before loading the sludge vessels. Decantation in this manner is practiced sparingly because of the adverse effect of the decanted liquor on the aeration tanks when the liquor is returned to the head of the plant.

Experience in New York City indicates that the rather common practice in smaller plants of concentrating excess activated sludge by wasting return sludge to the head of the primary tanks is not to be recommended unless the primary retention period is 2 hr or more. Shorter retention periods are apt to result in higher suspended solids in the effluent than in the raw sewage influent. Moreover, the septic character of the settled sewage is likely to be disturbing to the subsequent aeration process.

The motor vessels used in transporting sludge to sea are owned and operated by the city with a fixed personnel determined by U. S. maritime regulations. During 1941, each trip (1,500 wet tons) of sludge to sea cost about $202, for operating and maintenance charges. The cost of disposal of sludge to sea by the motor sludge vessels is estimated to be $3.13 per dry ton of solids transported, capital charges included. For New York City, sea disposal is the cheapest of methods available.

BOWERY BAY

The 40-mgd activated-sludge plant at Bowery Bay was started on primary treatment in November, 1939, but secondary activated-sludge treatment was not begun until March, 1942. During the early operations the raw primary sludge was barged to sea. Later, as the digesters were put in service, the combined primary and excess activated sludges were digested and the digested sludge in most part was barged to sea by Diesel sludge vessels as at Wards Island. However, substantial amounts of liquid digested sludge have been carted by specially designed motor tank trucks to the unimproved areas of Flushing Meadow Park (formerly the site of the New York World's Fair), there to be used for soil improvement after natural drying.

During the period of primary treatment only, the raw sludge transported to sea averaged 7.10% solids, but the density decreased in the subsequent year to an average of 5.38%. The Bowery Bay plant has primary tanks of 1-hr retention. Wasting excess activated sludge ahead of the primary tank is not practiced, although a rather heavy decanted liquor from digesters is so wasted, and has proved disturbing to the aeration process. The decreased density in 1942 was probably due to the effect of decanting and to a higher rate of sludge pumping.

For concentration of the excess activated sludge, the plant has two thickening tanks. Provision is made for thickening either the return sludge or the aeration tank effluent—the latter is practiced. The aeration effluent (line 11, Table 5) averaging 0.16% solids (suspended solids, 1,600 ppm) was concentrated in the thickening tanks to 2.40% solids, whereas the return sludge averaged 0.40% (suspended solids, 3,980 ppm). The weighted average of combined primary and excess activated sludge pumped to the digesters was about 4%.

Since the same sludge vessels serve Wards Island, Bowery Bay, and Tallmans Island, the cost of $3.13 per dry ton given for Wards Island therefore applies also to the Bowery Bay plant, although the distance is longer and the loading more time consuming.

The other method of sludge disposal, mentioned previously, may need more explanation. The need for organic soil building material by the extensive park system of New York City led to the purchase of three special motor tank trucks to serve future park areas with liquid digested sludge. The cost of disposal by these trucks is estimated to be $3.50 per ton of dry solids removed, capital charges included, on the assumption that the trucks are kept rolling, which is not the case under wartime conditions.

TALLMANS ISLAND

The 40-mgd activated-sludge plant on Tallmans Island was placed in service in 1939. It treats an average flow of 15 mgd. At this plant, as at Bowery Bay, the excess activated sludge is concentrated in two special thickening tanks before pumping to digesters. The thickeners can be fed only with return sludge. During the first five months of 1941, when sludge thickening was under careful study, the thickened excess activated sludge was wasted to the head of the primary tanks having a retention of about 2 hr, and was recovered with the primary sludge. In the second half of 1941, the excess activated sludge, after thickening, was pumped separately to the digesters. When pumping to digesters, an effort was made to obtain the secure maximum concentration.

Table 5(*d*) shows several interesting facts concerning these operations. During the period when excess activated sludge was wasted to the head of the plant, the primary solids averaged 5.41%, compared with 7.52% solids when excess activated sludge was excluded from the primary tanks. With a feed of return sludge averaging 0.51% solids (suspended solids, 5,100 ppm), the thickeners during the first period concentrated the sludge to 1.35% solids, as compared with 3.48% solids during the more exacting second period. Combined sludges to digesters averaged 6.41%.

The difference between the values shown in lines 22 and 23, Table 5, of "digested sludge to storage tanks" and "digested sludge to disposal" is due to further concentration in the storage tanks by decantation. The digested sludge at Tallmans Island has been partly barged to sea and partly transported by the tank trucks to Flushing Meadow Park.

SPECIAL THICKENING TANKS

The thickening tanks used at the Tallmans Island and Bowery Bay plants are of the conventional "picket fence" type. The Tallmans Island tank is illustrated in Fig. 8, and the Bowery Bay tank in Figs. 9 and 10. The main difference is that the Bowery Bay thickeners, later constructed, are shallower and of greater relative area. The Tallmans Island thickeners were each provided originally with a ring for introducing chlorine solution to the supernatant near the top of the tank, following the practice developed at certain western plants, but it was found that better results were obtained by discontinuing this arrangement and applying the chlorine solution direct to the

incoming sludge liquor. The distributing ring was omitted from the Bowery Bay and later designs.

The use of chlorine in connection with thickening is considered a helpful step during the summer months or on occasions when the settling characteristics of the sludge are not good. In general, chlorine helps when the dissolved oxygen in the entering liquor is low, the sludge index is poor, and the volatiles are high. Experience in New York City shows that better results can be obtained by thickening the aeration tank effluent in a single step than by rethickening the return sludge. This conclusion seems in agreement with the western experience, although apparently inconsistent with experience at Tallmans Island. It is recognized that the volatile content of activated sludge determines the degree of concentration possible.

At Tallmans Island, an effort to maintain a residual of 1.0 ppm in the overflow resulted in an average dose of 75 ppm of chlorine. At Bowery Bay, under wartime conditions, an average dose of 18 ppm of chlorine was used.

No residual chlorine was maintained in the overflow; hence the treatment could be considered only a palliative for a poor sludge condition and no answer to proper requirements.

CENTRIFUGE EXPERIMENTS

Aside from the usual operating methods described herein, it may be of interest to note some special experiments with concentrating sludges.

At the Jamaica (N. Y.) plant, a special centrifuge has been installed for the purpose of dewatering material caught by fine screens. During 1938 some thirty-five runs were made with this centrifuge on digested primary sludge from the Coney Island plant. The feed of the centrifuge averaged 11.1% solids; the cake, 50.2% solids; and the effluent, 3.4% solids. It was intriguing to find that within a few minutes digested sludge could be concentrated or partly dewatered to a friable inoffensive material ready to be hauled away and distributed on park areas, but the effluent from the centrifuge was still a sludge containing a high proportion of the grease, and no satisfactory way of disposing of this liquor was discovered.

At Wards Island in 1939, a continuous centrifuge was set up and experimented with to determine its possible utility for concentrating activated sludge. The following values were obtained on return sludge as feed:

Feed	Cake	Effluent
0.398%	4.72%	0.0932%

With excess sludge instead of return sludge as feed, the corresponding figures were:

Feed	Cake	Effluent
1.60%	2.59%	0.95%

Since the effluent of the centrifuge, as in the case of the Coney Island digested sludge, still presented a problem for final disposal, the experiments did not lead to any development along these lines.

Considerable study has been made on activated sludge in the laboratory in an effort to break down its gelatinous character, thus enabling the sludge to be separated from its voluminous water content. It is well known, of course, that ferric chloride of about 3% to 5% of the solids content will aid in this respect, but the cost of such treatment makes it adaptable only where sludge is to be dewatered on vacuum filters.

Some studies have been made of freezing methods suggested by John R. Downes of Plainfield, N. J., for dewatering primary digested sludge.[14] It was found that activated sludge could be concentrated to about 20% solids by freezing, quick thawing, and centrifuging. The liberated water, however, had to be separated immediately after each thawing, or the sludge became septic and less responsive to dewatering. The freezing method did not appear attractive for raw activated sludge.

DISCUSSION

C. R. Velzy,[15] M. Am. Soc. C. E.—The subject of this Symposium is important to the designer who is faced with the problem of providing economical sludge disposal. The authors have treated the subject from the viewpoint of operation and research, and make valuable contributions in stressing some factors that aid in concentration, and also in indicating other factors which appear to be of no assistance.

Mr. Goudey indicates that raw sludge is concentrated with the same percentages of chemicals as are needed for digested sludge and therefore concludes (see heading, "Conclusions") that, for sludge concentration, "* * * digestion is unnecessary and wasteful." Digestion is a step in sludge disposal involving a number of factors rather than merely one method of concentrating sludge. Among these factors are an appreciable reduction in the quantity of solids, elimination of nuisance in sludge disposal, production of combustible gas, and other aids to sludge disposal. The reduction in solids by digestion results in the use of smaller quantities of chemicals for dewatering solids from a given quantity of raw sludge. Although digestion may be considered a means of thickening sludge, the reverse is often true—the concentration of sludge, in many cases, is an aid to digestion.

In Table 2 Mr. Keefer shows operating results at Baltimore, which appear to involve some discrepancies. For example, in the 1941 data, a quantity of 22,520 gal of sludge, 1.1% solids, is shown going to the thickener. The solids in the thickener effluent are negligible. Whereas the concentration of sludge is somewhat less than two to one, the reduction in volume is more than five to one. Stated in another way, the solids withdrawn from the thickener do not balance the solids discharged into the thickener. It is well known that in sewage treatment it is difficult to obtain representative samples and data truly characteristic of the actual conditions. Is it possible that more concentration was accomplished than is indicated by the data? Some comments by Mr. Keefer might be helpful.

Although consideration in the Symposium, and in some earlier work, has been given to concentration of primary and digested sludges, there is relatively not much to be gained in these applications. Digested sludge can be sufficiently concentrated in the bottom of digestion tanks. As Mr. Donaldson states, the density of primary sludge can be controlled adequately by the pumping schedule, and it is even possible to obtain primary sludge too dense for pumping.

With activated sludge in which concentration is likely to be from 1% to 2% solids, there is room for considerable gain by concentration. Even moderate results may reduce the volume to a half, or a third, of the original volume, which is a real gain for digestion, barging to sea, or any other process of sludge disposal.

Of the several factors affecting concentration of activated sludge, only a few can be applied practically by the designer. Mr. Rudolfs has shown that compaction may be affected by the character of sludge, initial concentration, time, temperature, pressure, and the use of chemicals. Of these elements, time and the use of chemicals have a direct bearing on design. Initial concentration is a factor in design because provision may be made to concentrate waste sludge from final settling tanks or aeration tank effluent, or to use either method at the option of the operator.

---

[15] Asst. Engr., Greeley & Hansen, New York, N. Y.

Data in the several papers of the Symposium show that, at Los Angeles, Baltimore, and New York, satisfactory results in thickening activated sludge have been obtained. It is of interest to note that experience at Los Angeles and New York indicates that better concentration can be obtained by thickening aeration tank effluent than by thickening waste sludge. This fact permits simpler design and operation since the thickening tank can be built as a small unit of a group of final settling tanks, and an additional pumping operation on waste sludge is not required.

The designer at present finds a scarcity of conclusive data on sludge thickening. It is reasonably well established that time is a pertinent factor, but, over too long a period, sludge tends to become septic. This tendency can be controlled to some extent with chlorination. Other questions on which there is little information include the type of mechanism best adapted to concentrating and handling sludge, shape and size of sludge hoppers, and the degree of concentration to be expected. It is hoped that studies will be continued by operators having the facilities, and that particular emphasis will be placed on factors that may be incorporated in design and may be useful in operation.

R. F. GOUDEY,[16] M. AM. SOC. C. E.—Experience at the Los Angeles experimental sewage treatment plant, as previously discussed, indicates that, for a given volume of treated sewage, the chemical requirements for vacuum filtration of the fresh sludge and the equivalent requirements for the same fresh sludge digested are the same. It is realized that, volume for volume, digested sludge requires less chemical dosing than fresh sludge; but, considering the sewage producing fresh sludge and the corresponding reduced volume of digested sludge, the chemical doses are identical. It is quite logical, therefore, to question what advantage is actually gained from digesting sludge.

There are two purposes for digesting sludge: First, to obtain a sludge that can be dewatered on sand beds without creating a fly nuisance; and second, to obtain power. From the standpoint of fertilizing value, digestion reduces the nitrogen content from four to one per cent. On the other hand, chemically treated fresh sludge dewaters more rapidly than does digested sludge when placed on sand drying beds and does not create a fly nuisance. The chemically treated fresh sludge still retains a high nitrogen content but must be subjected to mold action for several months before it can be used satisfactorily as a fertilizer. Therefore, the broad question of whether or not sludge should be digested prior to chemical treatment seems far more involved than has yet been realized. It is hoped that further experiments in other parts of the United States will be made concentrating excess activated sludge under a chlorine blanket so that working knowledge of this superior method can be obtained firsthand.

WEDGE-SHAPED STRUCTURAL MEMBERS UNDER DIRECT STRESS AND BENDING

BY ROBERT B. B. MOORMAN,[1] ASSOC. M. AM. SOC. C. E.

WITH DISCUSSION BY MESSRS. PHIL M. FERGUSON, STANLEY U. BENSCOTER, GEORGE WINTER, WALTER H. WHEELER, LEON BESKIN, AND ROBERT B. B. MOORMAN.

SYNOPSIS

Presented in this paper are expressions for computing compressive and shearing unit stresses in the concrete, tensile unit stresses in the reinforcement, and bond unit stresses between the reinforcement and concrete for wedge-shaped reinforced concrete members subjected to direct stress and bending. Curves to expedite the use of the expressions are also presented. Only approximate solutions are offered since the materials do not follow strictly the assumptions made in the derivations.

INTRODUCTION

The subject of stresses in wedge-shaped reinforced concrete members subjected to direct stress and bending has been treated in relatively few papers. E. Mörsch[2] presented a derivation pertaining to the shearing unit stress for the case in which the compressive surface is normal to the section on which the stress is considered acting, and the reinforcement inclined to that section. Mörsch's treatment serves as a basis for the more extensive derivations of expressions for shearing unit stress and bond unit stress found in this paper. V. Dašek[3] presented expressions with which to compute the shearing unit stress at any point along a section of the member, especially on the compressive side of the neutral axis. However, the shearing unit stress as used in design is a measure of diagonal tension, and for this reason only the stress on the tensile side of the neutral axis is of interest. On the compressive side of the neutral axis the actual shearing unit stress (maximum) would be found to be equal to

one half the maximum compressive unit stress and would be acting on planes inclined at 45° to the compressive surface.

Notation.—The symbols used in this paper are defined where they first appear, either by text or diagram. They conform essentially to American Standard Letter Symbols for Mechanics, Structural Engineering and Testing Materials[4] and American Standard Letter Symbols for Mechanics,[5] prepared by committees of the American Standards Association, with Society representation, and approved by the Association in 1932 and 1942, respectively.

Assumptions.—The usual assumptions that are made in deriving the ordinary expressions in reinforced concrete design are:

(1) A section plane before bending remains plane after bending;

(2) The reinforcement resists all the tension;

(3) The unit stress in the concrete is proportional to the distance from the neutral axis and in the reinforcement it is n times the proportionality for the concrete, in which n is the ratio between modulus of elasticity of steel and modulus of elasticity of concrete; and

(4) Perfect adhesion exists between the concrete and the reinforcement.

BENDING STRESSES

Fig. 1 shows part of a wedge-shaped reinforced concrete member acted upon by an external force, R. This force can be resolved into components N (normal) and V (shear) as shown. The total compression on the section is indicated by C, and the component, normal to the section A–A, of the total tension in the reinforcement by T. The compressive unit stress normal to and at the edge of the section is shown as f_0.

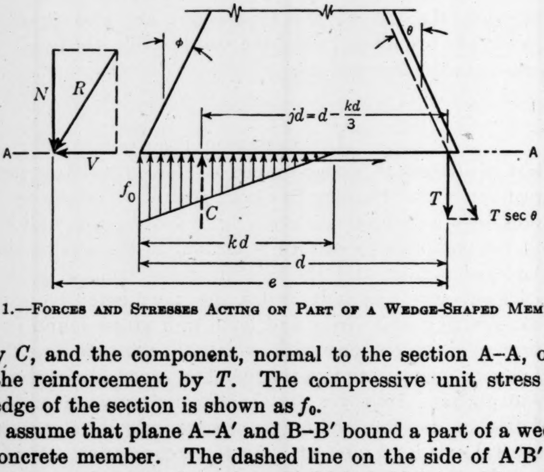

FIG. 1.—FORCES AND STRESSES ACTING ON PART OF A WEDGE-SHAPED MEMBER

In Fig. 2 assume that plane A–A′ and B–B′ bound a part of a wedge-shaped reinforced concrete member. The dashed line on the side of A′B′ represents the reinforcement. Assume that plane B–B′ is held in position while plane A–A′ is rotated through a very small angle α. The deformation, or change in length, of the reinforcement for length $\overline{rt}$ is $\overline{tu}$. Using the law of sines one may write

---

[4] ASA—Z10a—1932.

[5] ASA—Z10.3—1942.

$$\frac{\overline{tu}}{\sin(90-\alpha)}=\frac{d\,(1-k)\tan\alpha}{\sin(90+\alpha-\theta)}\ldots\ldots\ldots\ldots\ldots\ldots(1)$$

or

$$\overline{tu}=\frac{d\,(1-k)\tan\alpha\cos\alpha}{\cos(\theta-\alpha)}\approx\frac{d\,(1-k)\,\alpha}{\cos\theta}\ldots\ldots\ldots\ldots\ldots(2)$$

since α is so small that $\tan\alpha=\sin\alpha=\alpha$ and $\cos\alpha=1$, approximately. In Eqs. 1 and 2: d = the distance from the compression surface of the member to the center of the tensile reinforcement measured in the plane of section A–A; and k = the ratio of the distance from the neutral axis to the outer compressive fiber of a reinforced concrete member to the distance, d.

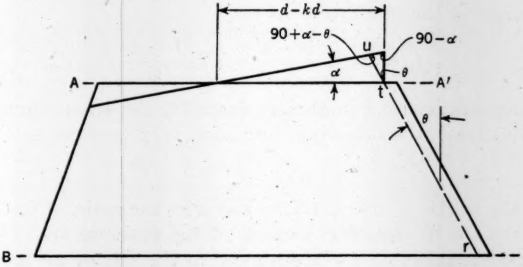

FIG. 2.—RELATION BETWEEN ANGLE CHANGE DUE TO BENDING AND DEFORMATION IN STEEL

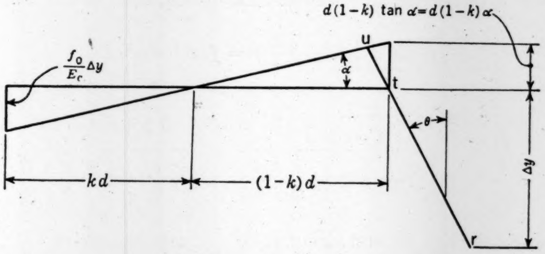

FIG. 3.—RELATION BETWEEN DEFORMATION OF CONCRETE AND DEFORMATION OF STEEL

Let Fig. 3 represent the deformations in length Δy. The angle α may be expressed in terms of the compressive unit stress in the concrete, f_0, normal to section A–A, as

$$\alpha=\frac{f_0\,\Delta y}{k\,E_c\,d}\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(3)$$

and, multiplying both sides of Eq. 3 by $d\,(1-k)$, Eq. 3 becomes

$$d\,(1-k)\,\alpha=\frac{f_0}{E_c}\,\frac{1-k}{k}\,\Delta y\ldots\ldots\ldots\ldots\ldots\ldots(4)$$

Now

$$\overline{tu} \approx d\,(1 - k)\,\alpha \sec\theta = \frac{f_0}{E_c}\,\frac{1 - k}{k}\sec\theta\,\Delta y \ldots\ldots\ldots\ldots (5)$$

and

$$\overline{rt} = \sec\theta\,\Delta y \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (6)$$

Therefore, the unit strain in the reinforcement can be expressed as

$$\frac{\overline{tu}}{\overline{rt}} = \frac{f_0}{E_c}\,\frac{1 - k}{k} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (7)$$

and the unit stress in the reinforcement as

$$f_s = E_s\,\frac{f_0}{E_c}\,\frac{1 - k}{k} = n\,f_0\,\frac{1 - k}{k} \ldots\ldots\ldots\ldots\ldots\ldots (8)$$

From a consideration of equilibrium (namely, the summation of vertical forces is equal to zero), the following expression may be written:

$$\tfrac{1}{2} f_0\,b\,k\,d = f_s\,p\,b\,d\cos\theta + N \ldots\ldots\ldots\ldots\ldots\ldots (9)$$

in which b = the width of the member; and p = the ratio of the area of the tensile reinforcement to the effective area of the concrete, $b\,d$. The area of the reinforcement is taken on a plane normal to the axis of the reinforcement.

Upon taking moments, about the point of application of the normal component of the resultant tensile stress in the reinforcement, of the forces acting on the section it is found that

$$\tfrac{1}{2} f_0\,k\,j\,b\,d^2 = N\,e \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (10)$$

Solving for N in Eq. 10 and substituting in Eq. 9,

$$\frac{1}{2} f_0\,k\,b\,d\left(1 - j\,\frac{d}{e}\right) = f_s\,p\,b\,d\cos\theta \ldots\ldots\ldots\ldots\ldots (11)$$

or

$$\frac{f_0}{f_s} = \frac{2\,p\cos\theta}{k\left[1 - \left(1 - \frac{k}{3}\right)\frac{d}{e}\right]} = \frac{2\,p\,\frac{e}{d}\cos\theta}{k\left(\frac{e}{d} - 1 + \frac{k}{3}\right)} \ldots\ldots\ldots (12)$$

Using Eq. 8 and Eq. 12 and eliminating $\frac{f_0}{f_s}$, one can write

$$k^2\left(\frac{e}{d} - 1 + \frac{k}{3}\right) = \frac{e}{d}\,(1 - k)\,2\,p\,n\cos\theta \ldots\ldots\ldots\ldots (13)$$

or

$$\frac{k^3}{3} + k^2\left(\frac{e}{d} - 1\right) + k\left(2\,p\,n\,\frac{e}{d}\cos\theta\right) = 2\,p\,n\,\frac{e}{d}\cos\theta \ldots\ldots (14)$$

Eq. 14 can be rearranged and a solution for $\frac{d}{e}$ computed as follows:

$$\frac{d}{e} = \frac{k^2 + k\,2\,p\,n\cos\theta - 2\,p\,n\cos\theta}{k^2\left(1 - \frac{k}{3}\right)} = \frac{3}{3 - k} + \frac{6\,(k - 1)}{k^2\,(3 - k)}\,p\,n\cos\theta \ldots (15)$$

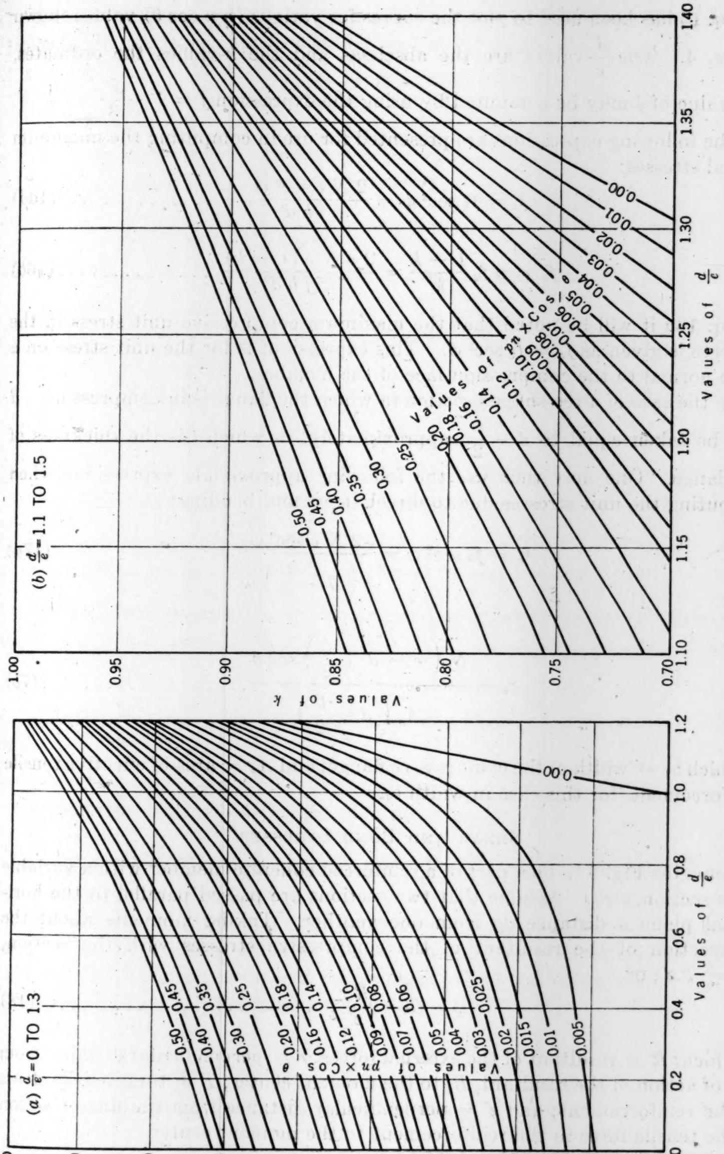

FIG. 4.—CURVES OF $\frac{d}{e} = \frac{3}{3-k} + \frac{6(k-1)}{k^2(3-k)} pn \cos \theta$

Eq. 15 has been used to plot the curves for various ($p\, n \cos \theta$)-values shown in Fig. 4. The $\frac{d}{e}$-values are the abscissas and the k-values the ordinates. The value of j may be computed by using the expression $j = 1 - \frac{k}{3}$.

The following expressions are presented for use in computing the maximum normal stresses:

$$f_c = f_0 \sec^2 \phi = \frac{2\, N\, e \sec^2 \phi}{k\, j\, b\, d^2} \qquad \text{(16a)}$$

and

$$f_s = n\, f_0 \frac{1 - k}{k} = \frac{2\, n\, N\, e\, (1 - k)}{k^2\, j\, b\, d^2} \qquad \text{(16b)}$$

In Eq. 16*a* it will be noted that the maximum compressive unit stress in the concrete is given as $f_c = f_0 \sec^2 \phi$. This expression[6] is for the unit stress on a plane normal to the compression face of the member.

In the case of a tee-shaped section in which the flange is in compression, $j\, d$ may be taken equal to $d - \frac{t}{2}$, approximately, in which t is the thickness of the flange. One may then use the following approximate expressions when computing the unit stresses due to direct stress and bending:

$$f_c = f_0 \sec^2 \phi = \frac{2\, N\, e \sec^2 \phi}{t \left(d - \frac{t}{2} \right) b_1} \qquad \text{(17a)}$$

and

$$f_s = \frac{N \left(e - d + \frac{t}{2} \right) \sec \theta}{A_s \left(d - \frac{t}{2} \right)} \qquad \text{(17b)}$$

in which b_1 = width of the compressive flange; and A_s = area of effective tensile reinforcement, for this case in width b_1.

SHEAR AND BOND STRESSES

Imagine Fig. 5 to be a part of a reinforced concrete member with a variable cross-section area. Assume that two sections are passed parallel to the horizontal plane a distance dy from one another. Taking moments about the intersection of the resultant of the compressive stresses with the section, $R\, r = T\, z'$; or

$$T = \frac{R\, r}{z'} \qquad \text{(18)}$$

in which: R = resultant of the external forces; r = perpendicular distance from line of action of the resultant, R, to the moment center; T = total tensile stress in the reinforcement; and z' = perpendicular distance from the line of action of the tensile force in the reinforcement to the moment center.

---

[6] "Earth Pressure, Walls and Bins," by William Cain, John Wiley & Sons, Inc., New York, N. Y., 1st Ed., 1916, p. 240.

Considering changes to take place only in T, r, and z', the change in tensile stress in the reinforcement in distance dy may be expressed as

$$dT = R\,\frac{z'\,dr - r\,dz'}{(z')^2} = \frac{R\,dr}{z'} - \frac{R\,r\,dz'}{(z')^2} \qquad (19)$$

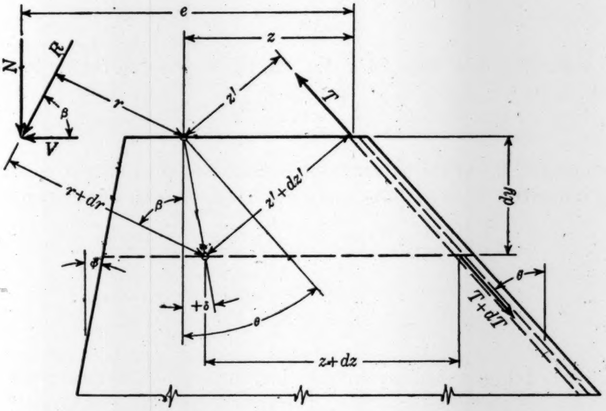

FIG. 5.—PART OF WEDGE-SHAPED MEMBER SHOWING MOMENT CENTERS

The following expressions for dr, dz', and z' may be derived from the geometrical relations (see Fig. 5):

$$dr = dy\cos\beta + dy\tan\delta\sin\beta \qquad (20a)$$

$$dz' = dy\sin\theta - dy\tan\delta\cos\theta \qquad (20b)$$

and

$$z' = z\cos\theta \qquad (20c)$$

Substituting Eqs. 20 in Eq. 19, the expression for dT is

$$dT = \frac{R\,dy}{z\cos\theta}\,(\cos\beta + \tan\delta\sin\beta) - \frac{R\,r\,dy}{z^2\cos^2\theta}\,(\sin\theta - \tan\delta\cos\theta) \qquad (21)$$

The differential tension, dT, in the reinforcement produces a unit shearing stress, v, in the adjacent concrete, which is parallel to the reinforcement, and an equal unit shearing stress v at right angles to the reinforcement.

If b is the width of the member, one may write

$$b\,v\,\frac{dy}{\cos\theta} = dT \qquad (22)$$

Substituting Eq. 21 in Eq. 22 and simplifying:

$$b\,v = \frac{R}{z}\,(\cos\beta + \sin\beta\tan\delta) - \frac{R\,r}{z^2}\,(\tan\theta - \tan\delta) \qquad (23)$$

From Fig. 4(*b*), also noting Eq. 18, it may be seen that

$$R \cos \beta = V \qquad (24a)$$

$$R \sin \beta = N \qquad (24b)$$

and

$$\frac{R\,r}{z \cos \theta} = T \qquad (24c)$$

Upon substitution of Eqs. 24 in Eq. 23, the expression for $b\,v$ becomes

$$b\,v = \frac{V + N \tan \delta}{z} - \frac{T\,(\tan \theta - \tan \delta)}{z} \cos \theta \qquad (25)$$

or, if the moment $R\,r$ of the external forces with respect to the selected moment center be indicated by M_0 (that is, $M_0 = z\,T \cos \theta$), Eq. 25 may be written as

$$b\,v = \frac{V + N \tan \delta}{z} - \frac{M_0\,(\tan \theta - \tan \delta)}{z^2} \qquad (26)$$

or

$$v = \frac{V + N \tan \delta}{b\,j\,d} - \frac{M_0\,(\tan \theta - \tan \delta)}{b\,(j\,d)^2} \qquad (27)$$

in which $j\,d$ = the distance, in the plane of the section, between the resultant of the compressive stresses and the resultant of the tensile stresses.

If it is desired to use the moment about the reinforcement as was done previously, the expression for M_0 becomes

$$M_0 = z\,T \cos \theta = R\,r = N\,(e - z) = N\,(e - j\,d) \qquad (28)$$

and substitution in Eq. 27 results in

$$v = \frac{V}{b\,j\,d} + \frac{N \tan \theta}{b\,j\,d} - \frac{N\,e}{b\,(j\,d)^2} (\tan \theta - \tan \delta) \qquad (29a)$$

In the case of a tee-shaped cross section, if the tee is on the compressive side, the position of the resultant of the compressive stresses changes so slightly with respect to the tee that $\tan \delta$ may be taken equal to $\tan(-\phi)$ without appreciable error. Eq. 29*a* can then be written as

$$v = \frac{V}{b'\,j\,d} + \frac{N \tan \theta}{b'\,j\,d} - \frac{N\,e}{b'\,(j\,d)^2} (\tan \theta + \tan \phi) \qquad (29b)$$

in which b' = the width of the stem of the tee-shaped member.

The expression for the unit bond stress, u, may be written

$$u = \frac{dT}{\dfrac{dy}{\cos \theta} \Sigma_o} = \frac{b\,v}{\Sigma_o} \qquad (30)$$

since, from Eq. 22, one has $\dfrac{dT}{\dfrac{dy}{\cos \theta}} = b\,v$. For rectangular sections, using

Eq. 29*a*, the expression for *u* becomes

$$u = \frac{V}{j\,\Sigma_o\,d} + \frac{N \tan\theta}{j\,\Sigma_e\,d} - \frac{N\,e}{(j\,d)^2\,\Sigma_e}(\tan\theta - \tan\delta)\,........(31)$$

Eq. 31 may be used for tee-sections by substituting $-\phi$ for δ in the last quantity.

FIG. 6.—CHANGE IN POSITION OF RESULTANT COMPRESSIVE STRESSES

An approximate expression for $\tan\delta$ may be derived in the following manner: Since k varies so slightly with y, especially over a distance Δy, one may write (noting Fig. 6),

$$\Delta y \tan\delta = \frac{k}{3}[d + \Delta y\,(\tan\theta + \tan\phi)] - \frac{k\,d}{3} - \Delta y \tan\phi\,....(32)$$

Dividing by Δy the expression for $\tan\delta$ becomes

$$\tan\delta = \frac{k}{3}(\tan\theta + \tan\phi) - \tan\phi = k\left(\frac{\tan\theta}{3}\right) - j\tan\phi\,....(33)$$

ILLUSTRATIVE EXAMPLE

FIG. 7.—ILLUSTRATIVE EXAMPLE

normal to the plane of the paper, is resolved into vertical (N) and horizontal (V) components. Other data are given in Fig. 7. The computation procedure is as follows: A_s per foot = 1.5 sq in.; Σ_o per foot = 6 in.; $p = \frac{1.5}{48 \times 12} = 0.0026$; $n = 10$ (given); and $p\,n = 0.026$. Enter Fig. 4(a) with $p\,n \cos\theta = 0.0225$ and $\frac{d}{e} = 0.667$; read $k = 0.29$; and compute $j = 1 - \frac{k}{3} = 0.903$. Use Eq. 10 to compute $f_0 = \frac{2 \times 30{,}000 \times 72}{0.29 \times 0.903 \times 12 \times 48^2} = 596$ lb per sq in.

From Eq. 16a, $f_c = 596 \times 1.072 = 639$ lb per sq in.; and, from Eq. 8, $f_s = 5{,}960 \, \frac{0.71}{0.29} = 14{,}590$ lb per sq in. A value for $\tan\delta$ can be determined by use of Eq. 33 as equal to $0.29 \, \frac{0.577}{3} - 0.903 \times 0.268 = -0.186$.

The shearing unit stress (as a measure of the diagonal tension) can be computed using Eq. 29a; thus, $v = \frac{40{,}000 + 30{,}000 \times 0.577}{12 \times 0.903 \times 48} - \frac{30{,}000 \times 72 \times (0.577 + 0.186)}{12\,(0.903 \times 48)^2} = 37$ lb per sq in. The bond unit stress can be computed by use of Eq. 30 as $u = \frac{12 \times 37}{6} = 74$ lb per sq in.

CONCLUSIONS

Formulas have been developed for compressive, bond and shearing stresses in the concrete and for tensile stress in the reinforcement for wedge-shaped reinforced concrete members. These expressions are applicable to members subject to bending and direct stress. The formulas are correct in so far as the assumptions used in the ordinary flexural theory are applicable to reinforced concrete.

DISCUSSION

Phil M. Ferguson,[7] M. Am. Soc. C. E.—Sometimes the reasonableness of a conclusion is as reliable a measure of an equation's worth as the reasonableness of the assumptions underlying this equation. As one who accepts conclusions very reluctantly when they do not appear to lead to reasonable results, the writer confesses he had difficulty with this paper. The following comments are largely critical of the results obtained by the proposed method.

The author has attacked a complex problem in an interesting manner. However, when the reader reaches Eq. 14, defining the location of the neutral axis, and discovers that this equation involves the slope of the reinforcing steel but not the slope of the compression face of the concrete, questions are raised. According to this equation, no matter what the concrete face slope (angle ϕ in Fig. 1) may be, the neutral axis will be the same relative distance $k\,d$ from the compression face; and this equation then leads to the further conclusion that f_0 and f_s are also independent of ϕ. The writer does not believe that this is true. On the contrary, he believes that all three of these terms are influenced by ϕ, f_0 and k being influenced to a very significant degree. It is probable that the influence of either ϕ or θ, which defines the slope of the steel, will be small when these angles are small; but it also seems probable that the influence is considerable when either angle is large. It is chiefly for these larger angles that concrete designers need specialized formulas.

It is probable that the basic assumption that plane sections before bending remain plane after bending is not acceptable in this problem, as satisfactory as it may have proved in other cases involving members of constant depth. It may be that this is the source of the following serious discrepancies.

Another contributing factor may be an inconsistency in the treatment of deformations at the beginning of the paper. The author is careful to relate the deformation of the steel to a certain vertical deformation and to his angle α. He makes no corresponding attempt to relate the outside concrete fiber deformation to the angle α. Instead, Eq. 3 states a supposed relation between f_0 and α which assumes that the unit concrete deformation vertically will be given by f_0/E_c. This relation ignores the fact that, with the principal stress parallel to the sloping concrete face, there exists a compressive stress perpendicular to f_0; and this stress will be large for large values of ϕ. It would seem that Poisson's ratio can scarcely be excluded from this equation. Even if this modification were made, it would seem safer to establish α or $k\,d$ from the inclined edge deformation which is more surely known in terms of f_c. A different location for the neutral axis might result from this treatment. However, it is doubtful whether any treatment based on straight-line deformations can be used in the general fashion indicated by this paper when face angles are of interesting magnitude.

The author implies that no limitations on the relative or absolute values of ϕ and θ are necessary. In the author's illustrative problem shown in Fig. 7, horizontal section A–A might have been taken at some other slope provided proper adjustment in e, N, V, and p accompanied this different choice of section. If the theory presented in this paper is correct, the concrete stress f_c at the left face at point A should be equally well determined by the author's section or by other inclined sections through the same point. Since the author's conclusions appeared open to considerable doubt, the writer calculated f_c at point A by the methods of this paper using sections A–B and A–C (Fig. 8(*a*)). The author reported f_c to be 639 lb per sq in. when based on section A–A. The calculated value of f_c at the same point on section A–B is 810 lb per sq in., and on section A–C it is 595 lb per sq in. If this theory were correct, there would not be this spread of more than one third in the resulting value of f_c when only the slope of the section analyzed is altered. One must conclude that the formulas are not correct for all sections—possibly not correct for any section.

---

[7] Chairman, Civ. Eng., Univ. of Texas, Austin, Tex.

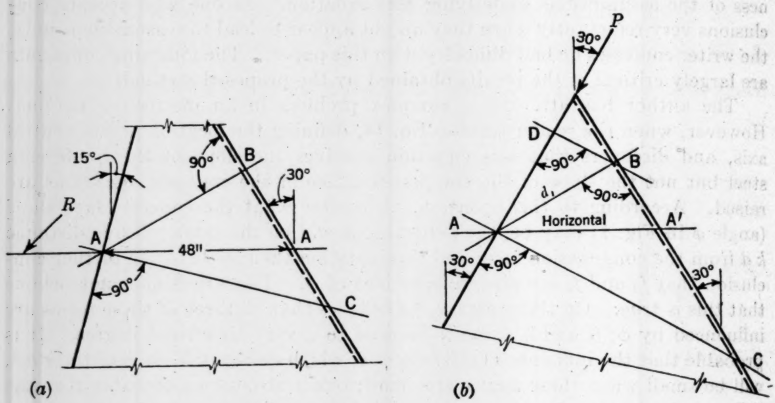

Fig. 8

To investigate this matter further, another wedge-shaped member was loaded in simple fashion, as shown in Fig. 8(*b*). With the load acting along one face, comparative analyses were simplified. The maximum concrete stress f_c at point A was calculated by the author's method applied to sections A–A′, A–B, and A–C. The steel stress f_s at point B was also calculated with sections A–B and D–B. The depth of section A–B was designated as d_1; the area of steel A_s was taken as 0.01 $b\ d_1$. The results show even more spread than in the foregoing case. A correct theory should give identical values of f_c and identical values of f_s for the points shown in Table 1.

Such divergent results lead to the conclusion that, until this method can be modified to give more consistent results on different sections, or until those sections are designated on which it may properly be used, the method must be rejected as one producing inconsistent results.

No lengthy comment will be made on the bond and shear formulas since these formulas must be subject to the errors of the bending formula. However, attention should be directed briefly to the theory behind the shear formula, because it might lead to unsafe design even when based on a correct tension formula. The author uses the shear adjacent to the steel as a measure of diagonal tension. This shear is not the largest shear in the case of a beam subjected to direct stress and bending. A larger shear exists within the compressive area, even in the case of a parallel sided member.[8] Moreover (although this is contrary to the conclusion of Stanley U. Benscoter and Samuel T. Logan, Juniors, Am. Soc. C. E.[8]), this larger shear will produce a considerably larger diagonal tension in the compression zone near the neutral axis than exists between the neutral axis and the steel. The small compression stress acting in this zone does make the diagonal tension smaller than the shear, but still leaves it greater than the lower shear value found near the steel. The shear adjacent to the steel is thus not a proper measure of the maximum diagonal tension and the author should not have used it as such.

TABLE 1.—DISCREPANCIES IN CALCULATED STRESSES

BASED ON SECTION:		Computed f_v	Computed f_c at point A	Computed f_s at point B
Fig. 8(*b*)	Description			
A–B	Perpendicular to steel	$2.05\ P/b\,d_1$	$8.20\ P/b\,d_1$	$12.86\ P/b\,d_1$
A–A′	Horizontal	$3.22\ P/b\,d_1$	$4.32\ P/b\,d_1$	....
A–C	Perpendicular to compressive face	$2.67\ P/b\,d_1$	$2.67\ P/b\,d_1$	....
D–B	Perpendicular to compressive face	....	....	$51.6\ P/b\,d_1$

S. Timoshenko[9] shows that large shears will accompany bending of a wedge-shaped beam of homogeneous material. In the case of a 15° slope of each face he shows that the maximum unit shear on a section perpendicular to the axis of symmetry is some 90% greater than on a beam of the same depth with parallel faces. This result does not necessarily apply to a reinforced concrete beam; but it should make one very conservative in the calculation of unit shears to be used as a measure of diagonal tension in the case of any member with sloping sides.

STANLEY U. BENSCOTER,[10] JUN. AM. SOC. C. E.—The concrete designer will find in this paper a group of formulas, for wedge-shaped members, developed on the basis of reasonable assumptions. Due to the lack of such formulas, internal stresses have been commonly computed for wedge-shaped members by using formulas and methods which should be applied only to prismatic members. The writer has been guilty of such erroneous stress analysis and has witnessed the same error by many designers. The Joint Committee Code renders little assistance in the analysis of combined stresses in wedge-shaped members, and it is of real value to the profession that formulas should become available.

It is possible to study the individual terms of some of the formulas and equations developed in this paper and thereby to establish some rules for design which tie in closely with past experience in the design of prismatic members. The cubic equation which governs the location of the neutral axis for a prismatic beam is well known. An examination of Eq. 14 indicates that one may replace the tensile steel area A_s, or the tensile steel area ratio p, by $A_s \cos \theta$ or $p \cos \theta$, respectively, and the cubic equation for prismatic beams will become the cubic equation for a tapered beam. This gives a simple rule for design. Project the normal cross section of the steel rods into the plane of the beam cross section to obtain a reduced steel area. Then calculate the neutral axis location just as for a prismatic beam. This rule is as applicable to compressive steel as to tensile steel. In the case of compressive steel, $(A_s)'$ and p' are replaced by $(A_s)' \cos \phi$ and $p' \cos \phi$, in which $(A_s)'$ and p' refer to the compressive steel area.

[10] Associate Engr., Bureau of Aeronautics, Washington, D. C.

In solving the cubic equation for k a designer usually estimates the first significant figure correctly but seldom guesses the second significant figure correctly in an initial estimate. The graphs of Fig. 4 will give the second significant figure for members without compressive steel and will probably give a good estimate in most cases for members with compressive steel. They are equally useful for prismatic or tapered members. The third significant figure may be obtained from a few cycles of trial and error or by iteration computations. In research studies of shear and bond stresses the normal stresses must be computed accurately at sections 1 in. apart and a fourth significant figure for k is generally desirable.

Before considering the individual terms of the formulas for shear and bond stresses it is profitable to recall the formulas recommended by the Joint Committee Code for wedge-shaped members without thrust. The usual formulas for shear and bond stress for a prismatic beam may be used if the shear V is replaced by the modified shear V_1 given by,[11]

$$V_1 = V \pm \frac{M}{d} (\tan \theta + \tan \phi) \quad \text{.............. (34)}$$

in which the negative sign is to be used when the depth of the beam increases in the direction of increasing bending moment; and θ and ϕ are the angles, respectively, that beam faces make with a direction normal to the direction of the external shear. It is not difficult to see that this definition of θ and ϕ is sensible only in the case of a beam without thrust and cannot be extended to a beam-column such as a member of a rigid frame. In the case of a haunched beam-column, loaded normal to its straight surface, it is common practice to calculate stresses on a cross section normal to the loaded surface, thus assuming θ to be zero in regions of negative moment. Perhaps it would be more accurate to calculate the stresses on a plane that is normal to the bisector of the wedge angle. No matter what direction of cross section is considered by the designer as the one on which flexural theory will give the most accurate stress determination, the resultant force may be resolved into a normal and tangential component. The expression "external shear" creeps into the Joint Committee Code at several points, thus causing considerable confusion.

---

[11] "Recommended Practice and Standard Specifications for Concrete and Reinforced Concrete," Rept. of the Joint Committee on Standard Specifications for Concrete and Reinforced Concrete, *Proceedings*, Am. Soc. C. E., June, 1940, Pt. 2, p. 56.

If the coefficient $\frac{M}{d}$ in Eq. 34 is replaced by $\frac{M}{j\,d}$, the formula has a simple rational explanation. This explanation has been given by the Joint Committee Code by stating that[12] "the resultant internal shear at any section is increased or decreased by the vertical components of the inclined stresses (tension or compression) * * *." Since $\frac{M}{j\,d}$ equals the normal tension T' or compression C' on a section without thrust, Eq. 34 may be modified to read (using the negative sign):

$$V_1 = V - (T' \tan\theta + C' \tan\phi) \qquad (35)$$

The normal forces T' and C' are components of the inclined forces T and C. Thus the terms $T' \tan\theta$ and $C' \tan\phi$ are components of T and C in the plane of the cross section. The force T acts along the center line of the tensile bar (or bars) whereas the force C acts parallel to the external surface in the compressive region. It would appear more reasonable if the angle ϕ were replaced by the angle $-\delta$ as introduced by Mr. Moorman, so that C acts along the line of centroids of the compressive stresses. The formula for δ as given by Eq. 33 may also be used for members without thrust.

It may be shown that Eq. 29*a* for v can be expressed in terms of the modified shear V_1 as given by Eq. 35. Regrouping the terms of Eq. 29*a* gives,

$$v = \frac{V}{b\,j\,d} - \left[\frac{N\,(e - j\,d)}{b\,(j\,d)^2} \tan\theta + \frac{N\,e}{b\,(j\,d)^2} \tan(-\delta)\right] = \frac{V_1}{b\,j\,d} \qquad (36)$$

in which

$$V_1 = V - [T' \tan\theta + C' \tan(-\delta)] \qquad (37)$$

When a section carries thrust as well as bending, the forces T' and C' are not equal but must be computed separately. Eq. 37 gives the designer a convenient rule for determining the shear and bond stresses in agreement with the assumptions of Mr. Moorman's analysis.

There are upper limits on the angles θ and ϕ beyond which the assumption of linear strain provides too much error. It is also known from the theory of elasticity that, in wedge-shaped beams, the shearing stresses have distributions which are greatly different from those in prismatic beams. The error involved in neglecting the rate of change of k along the member in evaluating δ from Eq. 32 is not known. These matters remain for future research study. It may be noted that, according to Eq. 33, the angle δ becomes zero when θ and ϕ are zero. Actually the angle δ is not zero for a prismatic beam that carries thrust. This error enters in due to the neglect of the rate of change of k along the member in writing Eq. 32. Neglecting the rate of change of j along the member leads to the Joint Committee Code formula, Eq. 34, and the formula is thus slightly in error.

GEORGE WINTER,[13] M. AM. SOC. C. E.—The ingenuous analysis of an important problem, as presented in this paper, is based on the assumption that plane sections remain plane in the deformed or stressed state of the members. This assumption is rigorously true for beams in pure bending. For transversely loaded beams it can be shown that the error introduced by such an assumption is insignificant provided the span : depth ratio is not too small. For beams of span : depth ratio smaller than about 3, such as occur occasionally in bunkers when the vertical walls are designed as beams spanning between supporting columns, the assumption of a straight-line strain distribution leads to very substantial errors.[14] This is true despite the fact that, in such beams, edges are parallel.

---

[12] "Recommended Practice and Standard Specifications for Concrete and Reinforced Concrete," Rept of the Joint Committee on Standard Specifications for Concrete and Reinforced Concrete, *Proceedings* Am. Soc. C. E., June, 1940, Pt. 2, p. 55.

[13] Asst. Prof., Civ. Eng., Cornell Univ., Ithaca, N. Y.

In the case of a wedge-shaped member it appears pertinent to question whether the assumption of a straight-line strain distribution can be expected to give reasonably accurate results, for the following two reasons: (*a*) In such members, except for very small wedge angles, the ratio of length of element to average depth of cross section is rather small—by analogy with the aforementioned prismatic beams, one may then expect a nonlinear strain distribution for essentially identical reasons; and (*b*) in addition, the sloped shape of the member is likely to introduce further deviations from the familiar situation in long, shallow prismatic beams.

It is customary to assume that the strain distribution in a reinforced concrete member is the same as that in an analogous member made of homogeneous material. This enables one to apply the results of the theory of elasticity of such homogeneous members without substantial change to the design of reinforced concrete structures. Although it is likely that this assumption is not strictly correct, it has proved its worth in practical application. Proceeding on this assumption, it is necessary, in the present case, to investigate the strain distribution in a homogeneous, wedge-shaped member under bending plus thrust. The fundamental theory pertinent to this problem has been given by

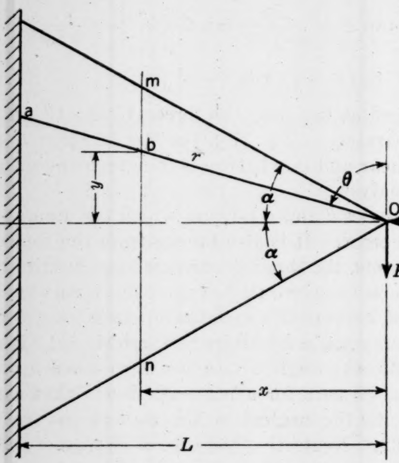

FIG. 9

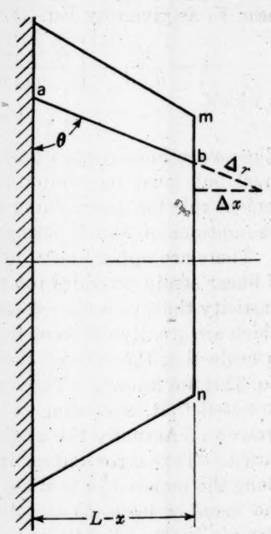

FIG. 10

---

[14] "Über den Spannungszustand in hohen Trägern und die Bewehrung von Eisenbetontragwänden," by Hermann Bay, Berlin, 1931.

S. Timoshenko,[15] who shows that, in a wedge loaded as in Fig. 9, the principal tension and compression stresses are directed radially. The author's case of bending plus thrust can be resolved into the two individual cases of transverse bending by a force P_1 in Fig. 9 and of longitudinal thrust by a force P_2. The stress-strain distribution due to simultaneous action of P_1 and P_2 is then obtained by simple superposition.

The strain distribution in bending due to P_1 will first be investigated. The magnitude of the radial stress at point b (Fig. 9), distance r from point O on a radius subtending the angle θ with the direction of the force P_1,[16] is

$$f_r = \gamma_1 \frac{\cos \theta}{r} \qquad (38)$$

in which

$$\gamma_1 = -\frac{P_1}{\alpha - 0.5 \sin (2\,\alpha)} \qquad (39)$$

is a constant depending on the wedge angle and the magnitude of the load P_1. Consequently, the radial strain is

$$\epsilon_r = \frac{\gamma_1}{E} \frac{\cos \theta}{r} \qquad (40)$$

To obtain the shape of an originally plane cross section mn (Fig. 9), it is necessary to calculate the change of length Δ_{ab} of a fiber of undistorted length ab (Fig. 10). This change of length is obtained by integrating the radial strain (Eq. 40) over the length of fiber ab. Thus,

$$\Delta_{ab} = \frac{\gamma_1 \cos \theta}{E} \int_{r_b}^{r_a} \frac{dr}{r} = \frac{\gamma_1 \cos \theta}{E} \log_e \frac{r_a}{r_b} \qquad (41)$$

in which r_a and r_b are, respectively, the radial lengths Oa and Ob (Fig. 9). From the angular relations of Fig. 9,

$$r_a = \frac{L}{\sin \theta} \qquad (42a)$$

and

$$r_b = \frac{x}{\sin \theta} \qquad (42b)$$

and, by substitution of these values in Eq. 41,

$$\Delta_{ab} = \frac{\gamma_1 \cos \theta}{E} \log_e \frac{L}{x} \qquad (43)$$

The horizontal component of the displacement Δ_{ab} of point b is

$$\Delta x = \Delta_{ab} \sin \theta = \frac{\gamma_1}{2\,E} \left[\log_e \frac{L}{x} \right] \sin (2\,\theta) \qquad (44)$$

On the other hand, the magnitude of the distance from the axis, y (Fig. 9), is

$$y = x \cot \theta = x \frac{\sin (2\,\theta)}{1 - \cos (2\,\theta)} \qquad (45)$$

A comparison of Eqs. 44 and 45 shows that, whereas y (the distance from the axis) is proportional to $\frac{\sin (2\,\theta)}{1 - \cos (2\,\theta)}$, the magnitude of the horizontal displacement Δx is proportional to $\sin (2\,\theta)$. It is thus established that, for the case of transverse bending, strains are not proportional to y in wedge-shaped members and that, consequently, originally plane cross sections become curved under such loading.

---

[15] "Theory of Elasticity," by S. Timoshenko, McGraw-Hill Book Co., Inc., New York and London, 1st Ed., 1934, pp. 93–95.

[16] *Ibid.*, Eq. 70, p. 94.

The shape of a cross section of a member subject to axial thrust is easily investigated in the same manner. With the angle θ as defined in Fig. 9, the radial stress in this case[17] is

$$f_r = \gamma_2 \frac{\sin \theta}{r} \qquad (46)$$

in which

$$\gamma_2 = - \frac{P_2}{\alpha + 0.5 \sin (2\,\alpha)} \qquad (47)$$

The horizontal component of the displacement, obtained by the same reasoning as before, is, in this case,

$$\Delta x = \frac{\gamma_1}{2\,E} \left[\log_e \frac{L}{x} \right] \sin^2 \theta \qquad (48)$$

This displacement is not constant over the cross section, but is proportional to $\sin^2 \theta$. Thus, as in the case of transverse bending, plane cross sections become curved in a wedge-shaped member subject to radial thrust.

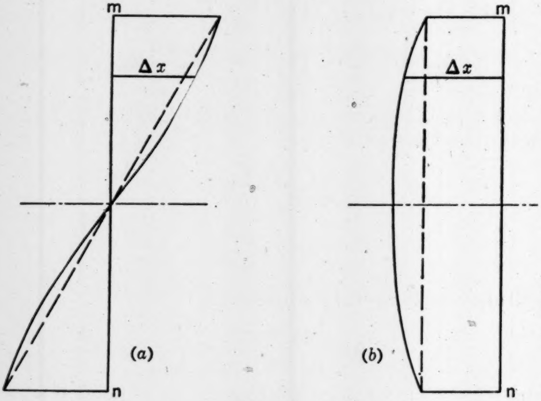

FIG. 11

To facilitate visualizing the magnitude of this effect, displacements were computed from Eqs. 43 and 48 for the case of a wedge with $\alpha = 30°$. The shapes of the distorted cross sections are plotted to scale—in Fig. 11(*a*) for transverse bending and in Fig. 11(*b*) for radial thrust. Even for this relatively small angle α, the deviations from planeness are substantial. For example, in the case of axial thrust, with $\alpha = 30°$, the horizontal displacement along the axis is one third larger than that at the outer fibers, whereas, if plane cross sections were maintained, these two displacements would have to be the same. Figs. 11(*a*) and 11(*b*) further show that in the case of simultaneous bending plus thrust, by superposition, the curvatures of the section subtract on the tension side, but add on the compression side. This complicates further the final shape of the cross section, which will also depend on the ratio $P_1 : P_2$.

---

[17] "Theory of Elasticity," by S. Timoshenko, McGraw-Hill Book Co., Inc., New York and London, 1st Ed., 1934, Eq. 69, p. 94.

An exact evaluation of the numerical influence of this distortion on the design values computed on the assumption of plane deformation is far beyond the scope of these sketchy comments. The numerical magnitude of the aforementioned discrepancies suggests, however, that practical application of the author's findings should probably be delâyed until a more rigorous investigation of this problem becomes available.

WALTER H. WHEELER,[18] M. AM. SOC. C. E.—Lucidly and commendably, the author has developed for the use of the profession a comparatively simple set of formulas, for which he does not claim 100% accuracy. However, the formulas are accurate enough for practical purposes, and they are simple.

Although wedge-shaped members are not common in the average type of structure they do, or can, occur frequently in retaining walls (especially high ones), bridge piers, and abutments.

The writer suggests that, in his closure, the author indicate how the analysis could be modified to apply to pyramidal structures.

LEON BESKIN,[19] ASSOC. M. AM. SOC. C. E.—The equilibrium of a wedge is usually considered only in the case of forces applied at the apex. The general loading must include the effect of a pure couple. Even more general loading conditions could be examined. This problem has been analyzed by J. H. Michell[20] for the case of a plane element limited to two radii and to two concentric circles, and Mr. Michell's analysis has been completed by the writer.[21]

The problem is too general in scope to be examined herein. It involves an analysis of the influence of the loading distribution on the stress distribution. This influence is disregarded in the conventional analysis of straight beams. For such an analysis, the stress distribution is assumed to be a function only of the resultant

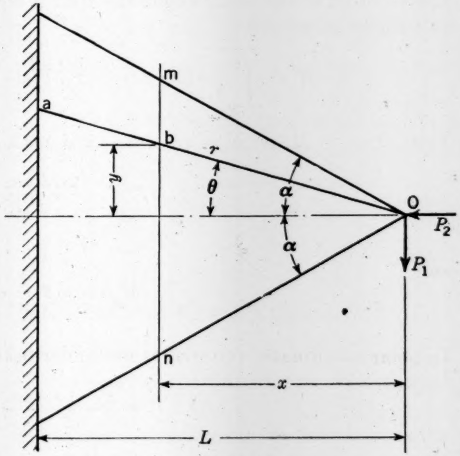

FIG. 12

---

[18] Designing and Cons. Engr., Minneapolis, Minn.

[19] Structures Engr., Consolidated Vultee Aircraft Corp., San Diego, Calif.

[20] *Proceedings*, London Mathematical Soc., Vol. 31, 1899, p. 100.

[21] *Comptes Rendus*, Académie des Sciences, Institut de France, Vol. 204, 1937, p. 1161.

of the loads and the moment about the centroid of the section at which the stresses are computed. For the same reasons as those given for straight beams, these effects will be neglected herein, and the problem will be limited to the case of a couple applied to the apex. The form of the corresponding stress function has been established by Mr. Michell[20] and reported by S. Timoshenko.[22]

For the case of a pure couple, the necessary terms of the stress function are:

$$\phi = a'_o \, \theta + d'_2 \sin 2\,\theta \ldots\ldots (49)$$

The corresponding stress components (see Fig. 12) are:[23]

$$\sigma_r = \frac{1}{r}\frac{\partial \phi}{\partial r} + \frac{1}{r^2}\frac{\partial^2 \phi}{\partial \theta^2} = -\frac{4\,d'_2}{r^2}\sin 2\,\theta \ldots\ldots (50a)$$

$$\sigma_\theta = \frac{\partial^2 \phi}{\partial r^2} = 0 \ldots\ldots (50b)$$

and

$$\tau_{r\theta} = -\frac{\partial}{\partial r}\left(\frac{1}{r}\frac{\partial \phi}{\partial \theta}\right) = \frac{1}{r^2}\,(a'_o + 2\,d'_2 \cos 2\,\theta) \ldots\ldots (50c)$$

Assuming that the shear is equal to zero along the two faces ($\theta = \pm\,\alpha$), the constant a'_o is defined as a function of d'_2 and the expression for the shear becomes:

$$\tau_{r\theta} = \frac{2\,d'_2\,(\cos 2\,\theta - \cos 2\,\alpha)}{r^2} \ldots\ldots (51)$$

The moment of the shear about the apex is equal to the applied couple M, per unit thickness of plate:

$$M = \int_{-\alpha}^{\alpha} r\,\tau_{r\theta}\,(r\,d\theta) = 2\,d'_2\,(\sin 2\,\alpha - 2\,\alpha \cos 2\,\alpha) \ldots\ldots (52)$$

Thus, $2\,d'_2 = M/K$; $K = \sin 2\,\alpha - 2\,\alpha \cos 2\,\alpha$; and Eqs. 50 become:

$$\sigma_r = -\frac{2\,M \sin 2\,\theta}{r^2\,K} \ldots\ldots (53a)$$

$$\sigma_\theta = 0 \ldots\ldots (53b)$$

and

$$\tau_{r\theta} = \frac{M\,(\cos 2\,\theta - \cos 2\,\alpha)}{r^2\,K} \ldots\ldots (53c)$$

In polar coordinates the strains and deformations are:[24]

$$\epsilon_r = \frac{\sigma_r - \nu\,\sigma_\theta}{E} = \frac{\partial u}{\partial r} \ldots\ldots (54a)$$

$$\epsilon_\theta = \frac{\sigma_\theta - \nu\,\sigma_r}{E} = \frac{u}{r} + \frac{1}{r}\frac{\partial v}{\partial \theta} \ldots\ldots (54b)$$

---

[22] "Theory of Elasticity," by S. Timoshenko, McGraw-Hill Book Co., Inc., New York and London, 1st Ed., 1934, Eq. 77, p. 114.

[23] *Ibid.*, Eq. 34, p. 53.

[24] *Ibid.*, Eqs. 45, 46, 47, and 48, pp. 62–63.

and

$$\gamma_{r\theta} = \frac{\tau_{r\theta}}{G} = \frac{1}{r}\frac{\partial u}{\partial \theta} + \frac{\partial v}{\partial r} - \frac{v}{r} \tag{54c}$$

Substitution of Eqs. 53 in Eqs. 54 leads to the following expressions for the displacements:

$$u = \frac{2\, M \sin 2\,\theta}{E\, r\, K} \tag{55a}$$

and

$$v = \frac{M\,(1 - \nu)}{E\, r\, K}\,(\cos 2\,\theta - \cos 2\,\alpha) \tag{55b}$$

The component of the displacement parallel to the center line is

$$u_o = u \cos\theta - v \sin\theta = \frac{M \sin 2\,\theta}{2\, E\, x\, K}\,[(1+\nu)\cos 2\,\theta + 2 + (1-\nu)\cos 2\,\alpha] \tag{56}$$

in which the radius r has been replaced by the coordinate x along the center line.

Since there is a shearing deformation that adds its effect to that of the deformation due to normal stresses, it is useful to examine each deformation separately. This can be done by choosing $\nu = -1$, which defines a fictitious material that is absolutely rigid in shear. The corresponding deformation is

$$u'_o = \frac{M}{E\, x\, K}\sin 2\,\theta\,(1 + \cos 2\,\alpha) \tag{57}$$

Numerical values of u_o, u'_o, and $u_o - u'_o$ are given in Table 2 for a wedge with an angle $\alpha = 30°$. Three points dividing the half depth in equal elements are selected, thus permitting a direct comparison with a linear deformation. These results show definitely the limitations of the method suggested by Mr. Moorman.

TABLE 2.—COMPARISON OF LINEAR DEFORMATION WITH DEFORMATION CAUSED BY NORMAL STRESS AND SHEAR

Angle (θ)	Normal stress— $\frac{E\,x}{M}\,u'_o$	Shear— $\frac{E\,x}{M}\,(u_o - u'_o)$	Total— $\frac{E\,x}{M}\,u_o$	Linear deformation
30° 0′	3.80	0	3.80	3.80
21° 3′	2.94	0.30	3.24	2.53
10° 54′	1.62	0.31	1.93	1.27
0° 0′	0	0	0	0

For many practical purposes, however, it is probable that the errors introduced by the hypothesis of plane sections are not excessive, and are well within the range of the other countless approximations of conventional stress analysis. In the case of the illustrative example presented by the author, the linear distribution would lead to fiber stresses at the edge that would be greater than the actual fiber stresses, the difference being approximately 10%.

The writer feels that errors of 10% are acceptable and would not impair the safety of a structure, even if they were not on the conservative side. In addition, it must be noted that no better method is available, which makes the hypothesis of linear distribution imperative.

Robert B. B. Moorman,[25] Assoc. M. Am. Soc. C. E.—In general, the discussion of this paper is constructive. Technical advancement can be accelerated by such criticism.

Professor Ferguson believes that the angle ϕ should be included in Eq. 14, and the writer agrees. Professor Ferguson also demonstrates the multiplicity of results that can be obtained by selecting sections through a point on the compressive surface and at various angles thereto. Both of these faults can be corrected by following Mr. Benscoter's suggestion—namely, placing $\phi = \theta$. Then, throughout the derivation, ϕ and θ would be interchangeable. Eq. 29b would become

$$v = \frac{V}{b' j d} + \frac{N \tan \theta}{b' j d} \left(1 - \frac{2 e}{j d} \right) \ldots\ldots\ldots\ldots\ldots (58)$$

and Eq. 33 could be written

$$\tan \delta = \left(\frac{2 k}{3} - 1 \right) \tan \theta \ldots\ldots\ldots\ldots\ldots\ldots (59)$$

On this basis, the illustrative example of Fig. 7 can be recomputed (see Fig. 13) as follows: $p = \frac{1.5}{45 \times 12} = 0.00278$; $p n = 0.0278$; $p n \cos \theta = 0.0257$; and $\frac{d}{e} = \frac{45}{74.35} = 0.606$. In Fig. 4(a) read $k = 0.29$ and compute $j = 1 - \frac{k}{3} = 0.903$. Eq. 10 gives $f_0 = 572$ lb per sq in. From Eq. 16a, $f_c = 582$ lb per sq in.; from Eq. 8, $f_s = 14{,}000$ lb per sq in.; from Eq. 59, $\tan \delta = -0.334$; from Eq. 29a, $v = 41$ lb per sq in.; and, from Eq. 30, $u = 82$ lb per sq in.

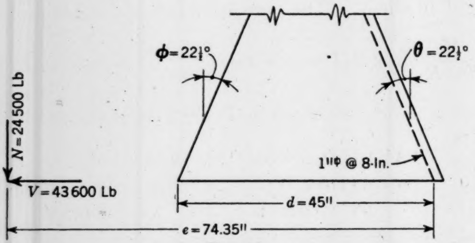

Fig. 13

Professor Ferguson states that "A larger shear exists within the compressive area * * *." He also states:

> "S. Timoshenko[9] shows that large shears will accompany bending of a wedge-shaped beam of homogeneous material. In the case of a 15° slope of each face he shows that the maximum unit shear on a section perpendicular to the axis of symmetry is some 90% greater than on a beam of the same depth with parallel faces."

Fig. 14(a) shows the distribution of such a unit shear, and it will be noted that Professor Ferguson's implication is quite misleading. The distribution of the unit shearing stress for a compressive load on the apex of a homogeneous wedge-shaped beam is shown in Fig. 14(b).

Mr. Benscoter gives some rules for design which should prove quite helpful. As he states: "There are upper limits on the angles θ and ϕ [now to be made equal] beyond which the assumption of linear strain provides too much error." The writer quite agrees and for this reason presents the data in Table 3. Although these data are for homogeneous beams, the practicing engineer can use them to determine the practical upper limit of θ. Referring to Fig. 12, the unit compressive stresses on section m–n due to the load P_2 may be expressed as

---

[25] Engr., Johns Hopkins Laboratory of Applied Physics, Silver Spring, Md.

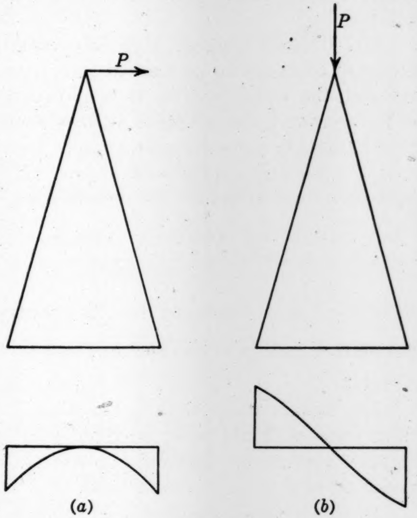
$$\sigma_x = -\frac{k_n P_2}{b\,d} \ldots\ldots (60)$$

in which b is the width of section; d is the depth at section m–n; and k_n is a constant in Table 3—k_1 for point 0.1 d from the axis, k_2 for point 0.2 d from the axis, etc.

The unit stress on section m–n due to bending caused by the load P_1, Fig. 12, may be expressed as

$$\sigma_x = \pm \frac{c_n P_1 x\, d}{I} = \pm \frac{M c_n d}{I} \,. (61)$$

in which I is the moment of inertia of section m–n $= \frac{1}{12} b\, d^3$; and c_n is a constant in Table 3—c_1 for point 0.1 d from the axis, c_2 for point 0.2 d from the axis, etc. The unit stress σ_x (for $n = 5$) should be multiplied by $\sec^2 \alpha$ to determine the maximum unit stress parallel to the surface.



(a) (b)

FIG. 14

TABLE 3.—COEFFICIENTS FOR USE IN EQS. 60, 61, AND 62

α	EQ. 60					EQ. 61					EQ. 62
	k_1	k_2	k_3	k_4	k_5	c_1	c_2	c_3	c_4	c_5	Q
5°	1.004	1.003	1.000	0.995	0.990	0.101	0.202	0.302	0.401	0.498	0.987
10°	1.018	1.011	0.998	0.981	0.960	0.103	0.205	0.304	0.399	0.488	0.952
15°	1.041	1.023	0.995	0.957	0.912	0.108	0.212	0.310	0.397	0.473	0.895
20°	1.074	1.041	0.989	0.923	0.847	0.115	0.223	0.317	0.395	0.453	0.820
25°	1.119	1.063	0.979	0.877	0.768	0.125	0.237	0.327	0.391	0.428	0.731
30°	1.176	1.088	0.962	0.820	0.679	0.138	0.255	0.339	0.385	0.398	0.631

Mr. Benscoter mentions problems that require future research. The writer would include the possibility of using the theory of plasticity as a basis for deriving equations comparable to those presented in the paper.

Professor Winter questions whether the assumption of a straight-line strain distribution can be expected to give reasonably accurate results. Essentially, the writer assumed straight-line stress distribution. His assumption was a practical expedient, and its accuracy can be gaged somewhat by use of the coefficients in Table 3. Specifications give allowable stresses with which to work, although it might have been more fitting to have developed specifications on the basis of allowable strains. Fig. 11 is interesting since it shows that the maximum strain for compression occurs at the position of minimum strain for bending.

Mr. Wheeler suggests that the writer indicate how the analysis could be modified to apply to pyramidal structures. Until some better method is developed, the writer believes that, if a section is taken perpendicular to the axis of the pyramid, the formulas as developed in the paper could be applied.

Mr. Beskin presents expressions for stresses and strains in a wedge for the case of a moment applied at the apex. By use of Eq. 53*a*, an expression for the maximum unit stress on the section m–n, Fig. 12, can be obtained as follows:

$$\sigma_r \text{ (max) } \cos^2 \alpha = \sigma_x \text{ (max) } = -\frac{M\,c}{I}\,\frac{\sin^3 2\,\alpha}{3\,K} = -\frac{M\,c}{I}\,Q \ldots\ldots (62)$$

in which c is the distance from the neutral axis to the extreme fiber; I is the moment of inertia of the section; and $Q = \frac{\sin^3 2\,\alpha}{3\,K}$. Values of Q are given in Table 3.

Mr. Beskin states that, in the illustrative example in the paper, the actual fiber stresses would be approximately 10% less than those computed by the method presented. The writer feels that, in general, conservative values would result from the use of the method.

In conclusion the writer would like to emphasize that (1) the angles ϕ and θ should be made equal, and (2) the coefficients in Table 3 can be used to gage the accuracy of the expressions presented.

AMERICAN SOCIETY OF CIVIL ENGINEERS

Paper No. 2265

PRIVATE ENTERPRISE

ANNUAL PRESIDENTIAL ADDRESS

By J. C. Stevens,[1] President, Am. Soc. C. E.

Some groups, both inside and outside of the government, seem to believe that the natural laws of economics can be repealed like man-made laws and one would almost think that they are trying to repeal them. Acting under those natural laws this country has made the nearest approach to Utopia ever recorded in history. In the face of this historic fact it appears somewhat absurd and futile to attempt to substitute an artificial economy controlled by administrative edict and bureaucratic regulations.

The Capitalistic System

This system, founded on the profit motive, has made the United States of America the outstanding nation of the world. We should not pussyfoot that statement but proclaim it boldly as a thing of which we have a right to be proud. That system produced the ships, the tanks, the planes, the munitions, the clothing, the foodstuffs that made it possible to outfit eleven million men and women and completely equip them for combat duty within a period of four years—an accomplishment unparalleled in the annals of the world.

Some may contend that the war capital was supplied by the government. Yes, but from whence came the government funds? The answer is obvious. They came from my earnings and yours and from those of every other taxpayer.

Let us face the facts. Private enterprise and the capitalistic system have, during the past 150 years, built the railroads; cleared the forests; built irrigation systems; cropped the lands; mined the coal, iron, and copper; launched ships; produced petroleum; erected the factories and power plants; designed and built automobiles, airplanes, caterpillar machinery; constructed highways; developed explosives, guns, electronics, communication systems; but, above all, they have produced officers of industry who, with the aid of free labor, knew how to turn their inventive and management genius to the business of winning a war. Patriotism supplanted profits and induced industry to carry on and produce in spite of many grueling regulations promulgated by well-intentioned but inexperienced and overlapping authoritative federal bureaus. Business has accepted this regimentation as a thing necessary to the war effort but is now demanding a respite which must be recognized.

---

[1] Cons. Hydr. Engr. (Stevens & Koon), Portland, Ore.

The capitalistic system and free competitive enterprise have made the winning of this war possible. That same capitalistic system, with the stimulus of free competition in cooperation with free labor operating under the natural economic laws of supply and demand, will make it possible to liquidate the unprecedented debt that now hangs, like the sword of Damocles, over this nation.

Any attempt to continue the artificial manipulation of prices and the harrowing control of management after the war necessity therefor has passed can only result in inflation with its consequent repudiation of values and its unthinkable social effects. Taxes must be reduced. The present hazards of conducting business efficiently must be eliminated. Surplus earnings must be allowed in some reasonable degree to provide for expansion of industry. Risk capital must foresee reasonable profits or it will not be forthcoming but remain nestled among government securities. If private enterprise cannot take the helm, the national income will sink to sickening levels and we will again find ourselves in a Slough of Despond.

Regulation

Wholesome and intelligent regulation, by law, of business activities to insure that they are carried on in a truly competitive field will have the continued support of the nation. Such affairs as the Insull and Foshay debacles must not again be allowed to besmirch the good name of well-conducted enterprise and give ambitious politicians the ammunition for broadsides against corporations in general, and honestly acquired wealth and competence in particular.

Private enterprise is the only system that can solve unemployment. To do so, however, it must be permitted a fair field, unshackled by excessive taxes and meddlesome regulations, and stimulated by a stable policy of fair dealing with only sufficient and intelligent control to insure that its operations are truly competitive. Under such conditions small businesses will spring up all over the country; a portion of profits will go back into the businesses; financing by private sources will be the order of the day; expansions will follow; new plants will be built; and unemployment will be reduced to a minimum.

In brief, unhampered private enterprise operating under a constructive labor policy, encouraged by a reasonable scale of rewards to both labor and management, will keep this nation operating with a high degree of business stability, balance the national budget, and pay off an unprecedented national debt.

The Engineer Holds the Stage

The engineer will play a most important rôle in the revitalization of the world for peacetime pursuits. His is the task of converting industry to produce consumer goods in lieu of war materiel and munitions. He must design the highways and airways, modern streamliners of rail and stratosphere, improved radio, television, automobiles and trucks, household appliances, office equipment, air-conditioned housing, modern buildings, industrial instruments, communication systems, bridges, tunnels, and subways. He must not only design, but he must prepare specifications, execute contracts, and supervise construction. He just about occupies the center of the stage all the time.

All these—and yet he is virtually without honor save among his own colleagues; as witness the recent National Council for International Organization at San Francisco. The list of organizations asked to send representatives as consultants occupied several typewritten pages and included labor unions, service clubs, Jewish, Catholic, and Protestant groups, lawyers, guilds, many social and professional organizations, but not one representative of either a national or local engineering society. And why? Because the engineer has not organized his profession into pressure groups. He devotes time to civic service only on special request. He can solve technical problems but is rarely consulted on human problems. Public relations for him are merely word sounds without an urge to action. Politics is almost anathema in his thinking. He appears to prefer being left alone in his own technologic world without fanfare or encomiums.

The engineer does not yet fully realize that his usefulness to humanity would be enormously increased if he would take public relations to himself as a problem to be solved in the same earnestness with which he approaches the solution of a technical problem.

The engineer is no dullard. In cultural matters and accomplishments he will easily march abreast of those in other vocations. He can and must broaden his social horizon if he hopes to play effectively his part in getting this turbulent world back on an even keel.

He should take an interested part in civic affairs; join service and social clubs; chambers of commerce; serve on committees; learn to speak effectively in public; become interested in people and tolerant of their opinions. He will soon find himself on important committees, on boards of direction in industry and finance; and his advice and counsel will be solicited on all important matters.

Private enterprise must be manned and managed by men of integrity, of analytical mind, of technical ability, of sound judgment; men who are cooperative with labor and who so conduct their businesses as to hold the support and confidence of the public. To such positions the engineer should aspire.

Such enterprises, so managed, can accomplish the objectives herein set forth of balancing the budget, of maintaining the national income at a high level, and of paying off the most staggering debt that has ever been faced by any country in the world. It is vital that the public and Congress recognize the full import of that potentiality and give private enterprise the opportunity to justify our faith in it.

MEMOIRS OF DECEASED MEMBERS

JOHN FRANCIS COLEMAN, Past-President and Hon. M. Am. Soc. C. E.[1]

Died June 3, 1944

John Francis Coleman was born on November 23, 1866, in the small community known as Church Hill, Jefferson County, Miss., approximately twenty miles northeast of Natchez, Miss., on his grandfather's plantation known as "Wyolah." He was the eldest boy in a family of three boys and two girls born to James Wood Coleman and Elizabeth Treeby (Chaffe) Coleman, who shortly after their marriage had migrated to Mississippi from Minden, La., the home of Mr. Coleman's mother.

Mr. Coleman's brothers, Charles Coleman and Wood Coleman, died in their early youth, leaving a family of three children—Mr. Coleman and his sisters, Annie and Grace.

Mr. Coleman's paternal grandfather was Dr. Francis B. Coleman, a physician, who was beloved throughout the community in which he practiced.

Mr. Coleman's great-grandfather arrived in the United States from Ireland in the latter part of the eighteenth century, a refugee from the tyranny of the British Government, carrying with him documents relating to the age-old struggle of Ireland for independence led and sponsored by his associate and intimate friend, the Irish patriot, Robert Emmett. Mr. Coleman's mother, Elizabeth Treeby Chaffe Coleman, was the daughter of John Chaffe and Penelope Annie (Hamilton) Chaffe. Mr. Coleman derived his name from his maternal grandfather, John Chaffe, and his paternal grandfather, Dr. Francis B. Coleman.

When Mr. Coleman was twenty, the death of his father on March 21, 1886, necessitated his assumption of responsibilities not usually borne by a youth of his age.

From boyhood Mr. Coleman had been impressed with the skill of his grandfather as a family physician, and it was his greatest ambition to become a surgeon. However, this ambition was thwarted at an early age because he had both to earn his own livelihood and to aid in the support of his family.

After graduation from what was then Boy's High School, a New Orleans (La.) public school in June, 1884, since financial circumstances precluded a college education, Mr. Coleman, at the age of seventeen, accepted his first professional appointment as rodman on the location and construction of the Guatemala Northern Railroad. He remained with this organization until July, 1885, when he returned to New Orleans.

---

[1] Memoir prepared by Robert J. Cummins and H. M. Gallagher, Members, Am. Soc. C. E., and Alonzo J. Hammond, Past-President and Hon. M. Am. Soc. C. E. (Mr. Hammond died on December 2, 1944.)

In September, 1885, Mr. Coleman became levelman on the location and construction of the Kansas City, Memphis and Birmingham Railroad (later part of the Frisco Lines), between Memphis, Tenn., and Birmingham, Ala., and was stationed at Aberdeen, Miss.

By diligent application and constant study, Mr. Coleman was soon advanced to positions of increased responsibility, finally being made resident engineer in charge of construction of approximately ten miles of grading and track laying.

At this period of his career Mr. Coleman became conscious of the embarrassing fact that he had been promoted over fellow members of his party, who were his seniors by a number of years, and he accordingly resolved to assume an older appearance by growing a beard. This Van Dyke beard, originally acquired to offset his youthful appearance, became a familiar mark of identification for Mr. Coleman and added immeasurably to his distinguished appearance.

Possessed of broad knowledge, a keen and photographic mind, and a magnetic personality, Mr. Coleman made friends wherever he went and to a host of his friends he typified a cultured Southern gentleman.

Upon completion of the Kansas City, Memphis and Birmingham Railroad between Memphis and Birmingham, Mr. Coleman accepted an appointment as assistant engineer on the construction of a smelting plant for the Philadelphia Smelting and Refining Company at Pueblo, Colo. He remained on this assignment until August, 1889.

In September, 1889, Mr. Coleman began his apprenticeship in hydraulic engineering when he became assistant engineer for the United States Engineers, making hydraulic observations on the Mississippi River and its tributaries. He remained with the United States Engineers until July, 1890. This assignment laid the foundation for his subsequent extensive experience on, and knowledge of, the Mississippi River and its control.

From July, 1890, to August, 1893, Mr. Coleman was assistant engineer for the Texas and Pacific Railway Company in responsible charge of both construction and maintenance of way, between Marshall, Tex., and New Orleans.

Contact with contracting operations often inspires young engineers to enlarge their experience by engaging in contracting themselves. Mr. Coleman was no exception, and in August, 1893, he became junior member of the contracting firm of Mott, Hanlon and Company, engaged in constructing earthwork levees and drainage facilities. This partnership was not successful, and in September, 1894, it was dissolved and Mr. Coleman returned to the practice of his profession.

The New Orleans and Western Railroad (later the New Orleans Terminal Company), a subsidiary terminal line of the Southern Railway Company, was being constructed at this time, and Mr. Coleman was appointed division engineer in charge of design and construction of interchange facilities, connecting the major trunk lines serving New Orleans, together with the construction of Chalmette Slip, a marine terminal on the Mississippi River built on the site of the Battle of New Orleans, fought in 1815 after peace between Great Britain and the United States had been declared.

In May, 1896, Mr. Coleman accepted his first and only political appointment as principal assistant city engineer for the City of New Orleans. During his four years in this assignment, the City of New Orleans undertook an ambitious program of drainage work, street paving, and other municipal improvements, the design and execution of which were under Mr. Coleman's immediate supervision and direction.

In January, 1900, Mr. Coleman began his career as a consultant by organizing the firm of Coleman, Malochee and Villere, specializing in civil, mechanical, and electrical engineering. This partnership was dissolved in the latter part of 1903. At this period of Mr. Coleman's career he was employed as engineer by the Board of Commissioners of the Port of New Orleans, an agency of the State of Louisiana, empowered by law to provide and administer port facilities within the Port of New Orleans.

The turn of the century witnessed the beginning of a change in transportation facilities serving the Port of New Orleans—the Mississippi River steamboat traffic was being gradually supplanted by a more modern means of river transportation, and New Orleans was becoming a seaport. Such a change demanded adequate shedded wharfage space to accommodate the foreign and domestic commerce which had replaced the local river traffic.

As engineer for the Board of Commissioners of the Port of New Orleans, Mr. Coleman was responsible for the design and construction of timber wharfs and steel frame transit sheds along the extensive New Orleans waterfront. These structures subsequently were standardized for the Port of New Orleans and served as models for many other port development projects throughout the United States.

In addition to serving as engineer for the Board of Commissioners of the Port of New Orleans, Mr. Coleman conducted a consulting practice, and was engaged on the following projects: Park improvements for Audubon Park in New Orleans; a water works and electric light plant for Hazlehurst, Miss.; a water works plant for Napoleonville, La.; irrigation and reclamation work for the Union Irrigation Company of southwest Louisiana; the reclamation of tidal overflow lands and subdivision for the New Orleans Land Company; and the construction of a race track for the New Orleans Jockey Club.

During 1907 and 1908, Mr. Coleman was chief engineer of the New Orleans Great Northern Railroad Company (later the Gulf, Mobile and Ohio Railroad Company) in charge of preliminary and location surveys, as well as of the construction of a single-track railroad between Jackson, Miss., and Slidell, La.

After he left the New Orleans Great Northern Railroad Company, the following projects represent some of his most important work as consulting engineer up to the declaration of war upon Germany in 1917: Construction of sawmill, narrow gage railroad, and industrial village for the Great Southern Lumber Company; design and construction of wharf and mechanical cargo handling equipment for the New Orleans Refinery of the American Sugar Refining Company; layout and plot plan of the City of Bogalusa, La.; construction of the Lafayette Branch of the Southern Pacific Lines between Lafayette and Baton Rouge, La.; opening and development of a large stone quarry in

Winnfield, La., for the Southern Mineral Company; and design and construction of storm sewer system and storm protection facilities for Port Arthur, Tex.

Ever mindful of his obligations in wartime and eager to contribute his share toward the winning of World War I, Mr. Coleman closed his office in November, 1917, following the declaration of war against Germany, and became general superintendent of the Chickasaw Shipbuilding and Car Company (a subsidiary of the U. S. Steel Corporation) near Mobile, Ala. This engagement involved the selection of the site for the large shipyard and supervision of the construction of shipbuilding facilities and ships, together with the construction of a village for employees and families with a population of five thousand, complete with sewerage, drainage, public utilities, and street railway accommodations to and from Mobile.

Upon the signing of the Armistice, Mr. Coleman returned to New Orleans in November, 1919, and with his son, Eugene Hunter Coleman,[2] M. Am. Soc. C. E., opened the office of the J. F. Coleman Engineering Company, conducting a general consulting practice. The firm was retained to supervise the liquidation of the International Shipbuilding Company of Pascagoula, Miss., which had become surplus property at the end of World War I in 1918. At this time, because of the demands for exports to the devastated countries of Europe, impetus was given to port development throughout the United States, and Mr. Coleman's previous experience with the Port of New Orleans was most valuable.

He served as a consultant for the following ports on the Atlantic Ocean and the Gulf of Mexico: Jacksonville, Fla.; Charleston, S. C.; Mobile, Ala.; Freeport, Tex.; Richmond, Va.; Houston, Tex.; Corpus Christi, Tex.; Beaumont, Tex.; and Lake Charles, La. In addition he was again retained by the Board of Commissioners of the Port of New Orleans as consulting engineer. In this capacity, Mr. Coleman was sent to Europe where he visited and inspected all the major ports of Northern Europe for the purpose of formulating and recommending a policy for the administration of the Inner Harbor Navigation Canal, built at New Orleans, connecting the Mississippi River with Lake Pontchartrain at a cost of $20,000,000.

Mr. Coleman's services as consultant on river hydraulics were retained in connection with: The diversion of the Brazos River in Texas, near its mouth; the control of the Mississippi River at Memphis to prevent damage to bridges; the control of Pearl River, near Columbia, Miss., to prevent the changing of its course; and the control of the Mobile and Tensaw rivers near Mobile to prevent damage to bridges.

In January, 1925, one of the writers (H. M. Gallagher) became a member of the firm of J. F. Coleman Engineering Company, and continued as a partner and intimate associate of Mr. Coleman until the latter's death.

Mr. Coleman, while attending an annual meeting of the Mid-South Section of the Society in Memphis in 1925, happened to be aboard the ill-fated steamer, *Norman*, inspecting improvements on the Mississippi River below Memphis, when the vessel capsized and eighteen lives were lost, including twelve distinguished members of the Society. The following account of the catastrophe[3] illustrates the fortitude and resourcefulness of the man:

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 100 (1935), p. 1635.

> "On May 8, 1925, a party of distinguished engineers set out from Memphis, Tenn., to inspect improvements on the Mississippi River. During the course of the trip, their vessel, the ill-fated *Norman,* capsized and many were lost including a dozen members of the Society. A number, however, struggled to a sandbar in the river. Some of the later arrivals on this island were amazed to find a group that had reached there earlier huddled around a driftwood fire. In that group was a man of moderate height, friendly eyes, with stubby beard and mustache, calmly smoking a cigar. This striking picture is a typical characterization of John F. Coleman—resourceful in emergencies, uncomplaining of his lot, calm in the face of difficulties, and rising superior to every handicap."

Following the record high water with the attendant disastrous flood conditions which prevailed throughout the Mississippi Valley in 1927, the United States Engineers formulated and had enacted into law what was known as the Jadwin Plan of Flood Control for the Mississippi River and some of its tributaries. One of the most important features of this flood control plan was the protection of the City of New Orleans from further flood hazard by the diversion of a considerable proportion of the floodwaters from the Mississippi River, at a point twenty-six miles above the city, so the floodwaters could be discharged into Lake Pontchartrain at gulf level. The construction of the Bonnet Carre spillway was proposed for this diversion, and Mr. Coleman was retained by the United States Engineers to advise them with respect to the foundations for the concrete structure.

In 1930 Mr. Coleman was appointed by the U. S. District Court at New Orleans as the engineer member of a board of three commissioners to hear testimony and formulate recommendations as to the amount of damage sustained by the Louisiana State Highway Department, the Yazoo and Mississippi Valley Railroad Company, the Illinois Central Railroad Company, the Louisiana and Arkansas Railway Company, and other interested public utilities as a result of the construction and operation of the Bonnet Carre spillway and floodway. All recommendations submitted by this board were sustained by the court.

In 1932 Mr. Coleman was retained by the Freeport Sulphur Company to advise on the type and adequacy of foundations for plant structures at Grande Ecaille and Port Sulphur, La., where large new sulphur deposits had recently been discovered. The site proposed for the plant was sixty-five miles below New Orleans, on the west bank of the Mississippi River, in the midst of a flat alluvial salt water marsh, subject to overflow from the Gulf of Mexico at high tide—a soil aptly described by the early French settlers in Louisiana as *prairie tremblante* or "trembling prairie," because of its unstable condition. The construction of this plant was perhaps one of Mr. Coleman's greatest achievements in his long and successful career. The foundations supporting the heavy loads imposed by the machinery and equipment of the power plant, boiler room, compressor buildings, storage tanks, and other buildings have remained comparatively stable with very slight subsidence since erection.

---

[3] *Civil Engineering,* January, 1936, p. 60.

Mr. Coleman continued in active practice as a consulting engineer until August, 1932, when he was appointed as one of five members of the Engineers Advisory Board of the Reconstruction Finance Corporation with offices in Washington, D. C. In this capacity, he served until the completion of the work for which he was engaged, returning to New Orleans to resume his practice in September, 1933. During this period funds for the construction of the Mississippi River Bridge at New Orleans were obtained from the Self-Liquidating Division of the Reconstruction Finance Corporation, and Mr. Coleman's knowledge of conditions at the site was invaluable in assisting the committee in making recommendations for the loan.

During 1934 and 1935, Mr. Coleman was executive vice-president and general manager of the Jefferson Lake Oil Company, in charge of all operations in connection with the production of sulphur and the exploration for new sulphur deposits.

In the fall of 1935, Mr. Coleman returned to his consulting practice. During the next succeeding three years, in association with Ralph Modjeski,[4] and Frank M. Masters, Members, Am. Soc. C. E., he was retained on projects by the New Orleans, Texas and Mexico Railway Company (Gulf Coast Lines) as well as by the Texas and New Orleans Railroad Company (Southern Pacific Lines). The former engagement concerned the design and construction of an extension to a railroad bridge over the Atchafalaya River at Krotz Springs, La. The latter project was for the design and construction of a double-track railroad swing bridge over Charenton Canal at Baldwin, La., a single-track through truss railroad bridge over Wax Lake Outlet near Franklin, La., and the raising of the single-track railroad bridge over the Atchafalaya River at Morgan City, La.

In August, 1938, Mr. Coleman returned to Washington, D. C., as engineer adviser to the Self-Liquidating Division of the Reconstruction Finance Corporation, and, with the approach of war in July, 1940, he was given the additional title of assistant chief engineer, Defense Plant Corporation, with its attendant responsibilities. He remained in Washington until his death.

Mr. Coleman's broad experience and sound judgment on all matters pertaining to both the vast engineering and the business problems confronting the Reconstruction Finance Corporation and Defense Plant Corporation were regarded with such esteem that officials of both corporations were prepared to accept his decisions and recommendations without question or further confirmation. The vastness of the responsibilities in connection with the defense and war programs, undertaken by the Defense Plant Corporation of which Mr. Coleman was an integral part, may be better visualized when it is revealed that the program included more than 2,200 projects, involving every conceivable type of production plant and facility, and cost more than ten billion dollars.

Although Mr. Coleman undertook certain full-time assignments, such as executive vice-president and general manager of the Jefferson Lake Oil Company and engineer adviser to the Reconstruction Finance Corporation, with the exception of his wartime service as general superintendent of the Chickasaw Shipbuilding and Car Company at Mobile, he maintained his office as consulting engineer in New Orleans continuously from the date of opening in January, 1900, until his death.

---

[4] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 106 (1941), p. 1624.

On November 12, 1890, Mr. Coleman was married to Annie Hardee Hunter, daughter of Col. S. E. Hunter, an attorney of Clinton, La., and Stella (Taylor) Hunter. Mr. and Mrs. Coleman had one son, Eugene Hunter Coleman, who died on February 12, 1935. Mr. Coleman is survived by his sister, Miss Annie Hamilton Coleman; two nieces, Mrs. J. P. Shaw and Mrs. R. G. Deane; and his daughter-in-law, Mrs. Eugene Hunter Coleman.

No recital of Mr. Coleman's achievements, as an engineer and a loyal true friend, would be complete without a record of his undying devotion to his beloved wife, who always accompanied him to meetings of the Society. Although Mr. Coleman's devotion to Society affairs was outstanding to all who knew him intimately, his untiring love and devotion to his wife were his most noteworthy characteristics. Mrs. Coleman was nearly as well known to the profession as Mr. Coleman. It was this devotion and concern over the condition of Mrs. Coleman, who suffered a stroke of apoplexy in Washington, D. C., on January 15, 1944, and who died on January 24, 1944, which caused Mr. Coleman to suffer a severe heart attack on January 22, 1944. He never recovered and died in Baptist Hospital in New Orleans. Mr. Coleman could not have been a more ardent suitor during his courtship of his beloved wife than he was at all times, particularly during the closing days of Mrs. Coleman's life. His wife's death deprived Mr. Coleman of that zeal for living which had in the past always sustained him.

He practiced his profession with the zeal of a religion, and was noted for his meticulous regard for professional ethics, as promulgated by the various engineering organizations of which he was a member. His engineering contemporaries bear witness to his honorable practice and his unfailing consideration for the viewpoint of the other engineer.

Although having been denied the opportunity of an advanced formal schooling, he was a master of the technique of his profession and an old-school gentleman of broad reading and culture, well versed in the humanities. Mr. Coleman's leisure time for the most part was devoted to his wife, but he was fond of a game of golf for the recreation and the pleasant companionship which this sport afforded. If he had any hobby, it might be said to be an omnivorous desire to read. Reading, combined with a retentive mind, gave Mr. Coleman breadth of knowledge and a liberal education. He had the remarkable ability to grasp the intricate details of a situation quickly, and, discarding irrelevant data, to reach a prompt and logical decision.

Mr. Coleman was an engineer who possessed to an unusual degree the ability to apply common sense to all problems. He was outspoken in his views and tenacious of his opinions, broad-minded in his judgment, intensely loyal to his host of friends, and gifted with the faculty of endearing himself to all who were fortunate enough to know him.

Mr. Coleman was a member of the Episcopal Church, and at the time of his death was a member of Louisiana Lodge No. 102, F. and A. M., Orleans Delta Chapter, Royal Arch Masons. In 1906 he became a member of Jacques

De Molay Commandery No. 2, Knights Templar, from which he resigned in 1929. During World War I, while stationed in Mobile, Mr. Coleman organized and was the first master of the Pontalpha Lodge No. 804, F. and A. M., at Chickasaw, Ala. He was active in all the activities and ceremonies until his return to New Orleans in 1919.

At the time of his death, Mr. Coleman was a charter member, honorary member, and past-president of the Louisiana Engineering Society. In 1920 he was elected a member of the American Institute of Consulting Engineers and served as president in 1928. He was president of the American Engineering Council for one term in 1934 and 1935, and was always an ardent supporter of this organization. He belonged to the American Railway Engineering Association.

Mr. Coleman served the Society as Director from 1915 to 1917, as Vice-President in 1918 and 1919, and as President in 1930.

When Mr. Coleman was President of the Society, *Civil Engineering* was started, and his interest and enthusiastic support of this publication were manifested at all times.

In recognition of his attainments in his profession, Tulane University of New Orleans conferred upon Mr. Coleman the degree of Doctor of Engineering in 1935.

At the time of his death Mr. Coleman was vice-president of the Eye, Ear, Nose and Throat Hospital of New Orleans. He was most interested in this institution and gave unsparingly of his time in fostering its development.

Mr. Coleman was elected a Member of the American Society of Civil Engineers on October 2, 1901, and an Honorary Member on October 14, 1935.

ALONZO JOHN HAMMOND, Past-President and Hon. M. Am. Soc. C. E.[1]

DIED DECEMBER 2, 1944

Alonzo John Hammond, the son of John W. and Mary Ann (Padgett) Hammond, was born at Thorntown, Ind., on April 23, 1869. He came from a family of builders. His great-grandfather lived in Anne Arundel County, Maryland, and his grandfather began the westward trek into West Virginia. His father went to Thorntown and was married there. Alonzo Hammond received his early education in the public schools of Frankfort, Ind., a few miles from his birthplace.

Mr. Hammond was graduated from Rose Polytechnic Institute at Terre Haute, Ind., in 1889 with the degree of Bachelor of Science. He received the degrees of Master of Science in 1894, Civil Engineer in 1898, and Doctor of Engineering in 1933. During college, his ability as a student was recognized early. He was graduated with highest honors, being awarded the Hemingway Medal for the highest standing in the entire course, in a class in which one other besides himself became an Honorary Member of the Society—John D. Galloway.[2] During his college days, Mr. Hammond was gaining practical experience working on railway extensions, but he found time to be a leader in general social activities.

---

[1] Memoir prepared by a Committee consisting of Charles B. Burdick, Chairman, Joshua D'Esposito, and Theodore L. Condron, Members, Am. Soc. C. E.

After graduation, he entered the employ of his father, who was an architect, serving for a short time as a draftsman and then resuming his studies at the Massachusetts Institute of Technology at Boston in 1890–1891.

Returning to Indiana, he at once became city engineer of Frankfort and, until 1898, was engaged in the design and construction of sewers, street paving, and city bridges. In 1898 he entered the office of the chief engineer, Terre Haute and Indianapolis Railroad Company, where he remained until 1901, as assistant engineer on masonry design for bridges and in charge of terminal facilities including freight and passenger depots at South Bend, Ind.

In 1901 he became city engineer of South Bend continuing until 1909, in charge of the design and construction of all municipal work under the control of the Board of Public Works, including sewers, street paving, a crematory, and a boulevard system. He also conducted a general consulting practice. In 1901 he became consulting engineer for the Indiana Railway Company in charge of surveys for the South Bend and Southern Michigan Railway from South Bend to St. Joseph, Mich.; design and construction of all bridges, track, and overhead construction on interurban lines from South Bend to Niles, Mich.; surveys for Indiana Western Railway from South Bend to Michigan City, Ind.; and construction from South Bend to New Carlisle, Ind. During his ten-year residence in South Bend, he designed miscellaneous projects including a sewer system, and hydroelectric power developments on the St. Joseph River at Elkhart, Ind., and at South Bend. He was bridge engineer for St. Joseph County and designed and constructed eight bridges across the St. Joseph River.

In 1911, since Mr. Hammond had had broad experience in various improvements pertaining to municipal public works, he was selected as chief engineer of the Bureau of Public Efficiency at Chicago, Ill.—a privately financed organization engaged in a study of public expenditures by the city. He then began his long residence in and near Chicago, which remained his home until he moved to Washington, D. C., in 1941.

In 1912 and 1913 Mr. Hammond served as engineer of bridges and harbors in the City of Chicago. During his tenure of office he directed extensive research which resulted in notable reductions in the cost of operating and maintaining the city's bridges and viaducts. The program of designing and constructing bridges which has been followed in the development of Chicago's celebrated bridge system was fostered under Mr. Hammond's supervision; and structural, mechanical, and artistic details of the Chicago type bridge were further perfected.

The original plans for the Michigan Avenue Bridge were drawn by Mr. Hammond's division in 1912, and the bridge as it stands at this time is substantially the same as that then conceived and planned. Many new projects were initiated in 1912—notably the 35th Street Trunnion Bascule Bridge and the 92d Street Trunnion Bascule Bridge. The Washington Street Bridge, begun in 1911, was practically completed during 1912. The final drawings of the Lake Street double-deck trunnion bascule bridge were started during 1912. This project, together with others, minor in character, required enlargement of the personnel and quarters of the designing section. The requisite arrangements were made without interfering with the routine maintenance and repair of existing structures.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 109 (1944), p. 1451.

In 1914 he was engaged as consulting engineer by the Chicago Union Station Company and charged with the preparation of the design and construction of public facilities such as sewers, streets, and viaducts for this $75,000,000 project. From 1917 to 1919, during World War I, he acted as chief engineer in charge of the design of some of the most important functions and facilities of the terminal project. For a number of years, Mr. Hammond was engaged actively in construction; and, for three years (1922 to 1925), he was chief engineer of James O. Heyworth, Inc., contractors, largely on the construction of hydroelectric plants on the Mississippi, Chippewa, and Fox rivers in Wisconsin. From 1925 to 1927, he was chief engineer of the Mellon-Stuart Company in the Chicago office, representing that company on the formulation of a large internal improvement program in Cuba.

After 1927, and until his employment by the War Department in 1941, he conducted an office as consulting engineer in Chicago. During this time he was retained by the City of Chicago on various projects, such as river straightening, dock walls, bridges, and viaducts, and by numerous other cities, principally in connection with grade separations and passenger and river-rail terminals. During the 1930's, he frequently prepared confidential reports relating to loans and grants to municipalities and corporations for various federal agencies.

During World War II, and the earlier defense program, Mr. Hammond devoted his entire time to public service—from January, 1941, until his death. He was consulting engineer to the chief of the Construction Division, War Department, advising on camps and cantonments particularly during the organization and early construction periods of this important part of the war program. Thereafter, he was appointed a member of the Construction Advisory Committee (later merged into the Construction Contract Board of the Construction Division), War Department. This committee had the important task of advising on the employment of engineers, engineering organizations, and contracting organizations for the huge construction program necessary to mobilize resources and man power for war. The construction program being well under way in July, 1944, he was assigned to duty with the Price Adjustment Section, Construction Division, acting as deputy chief of the section. In this capacity he was engaged in the renegotiation of War Department contracts.

No one not closely associated with war activities can appreciate the long hours of hard work necessitated by the war program and the strenuous defense program which preceded it. Mr. Hammond's labors were continuous practically from the inception of these programs up to and including the day of his death. He was a man of robust health, but the last year was particularly trying because of the failing health of his wife who preceded him in death by only six weeks.

He took his job seriously. In one instance when an important decision on a 20-mile railroad line had to be made quickly, he examined the entire line on foot in less than two days, traversing difficult country that would have taxed the strength of a man half his age. Throughout his life, his work was characterized by ability, untiring industry, and the faculty of coordinating his work with that of others. He had the character and personality that made friends and kept them.

Mr. Hammond's career as an engineer is a striking example of the influences of both heredity and environment. His father and his grandfather were architects. Thus, he inherited the instincts of a professional man and an aptitude in designing and directing construction. His association with his father, before and after his technical education in Rose Polytechnic Institute, directly led him in the path of successful engineering practice with high ideals of integrity and professional conduct. By supplementing his four-year course in civil engineering at Rose Polytechnic Institute, with a special postgraduate engineering course at Massachusetts Institute of Technology, Mr. Hammond showed his own appreciation of the benefits of widening his training. His eminent success in the profession should be an inspiration to young men to acquire a broad education and to set high ideals of professional aims and conduct for themselves.

Mr. Hammond devoted all his spare time for many years to the service of the Society. He was Director (1926–1928), Vice-President (1929–1930), and President (1933), and remained for two years on the Board of Direction as a Past-President. In addition to serving in these offices, he was active in many other lines of Society endeavor. For five years he served on the Society's Committee on Professional Conduct, for the last two years of this period as chairman. He was chairman of the committee which made a study of American Engineering Council in 1928. He was always a strong advocate of co-operation among engineers and served as the president of American Engineering Council (1940–1941) and as president of the Construction League (1933–1934). He was chairman of the Functional Expansion Committee which sponsored several nontechnical Society activities. He was closely associated with the expansion of the Local Sections and the activities of Juniors and Student Chapters. He was instrumental in fathering such committees as those on engineering education, public education, legislation, and registration of engineers in public and quasi-public offices.

His work for engineers did not stop with the completion of his term on the Board of Direction of the Society. His service to the engineering profession is well stated in his citation for Honorary Membership which calls him "* * * Servant of the Society and other great professional bodies, increasingly honored by his fellow engineers for his personal qualities and his technical ability * * *." He also belonged to the American Institute of Consulting Engineers (vice-president in 1943), the Western Society of Engineers, the American Railway Engineering Association, the Indiana Society of Engineers, the Chicago Engineers Club, and the Shawnee Country Club.

Among other activities, Mr. Hammond found time to serve his alma mater, Rose Polytechnic Institute, as alumni member of the Board of Managers, from 1917 to 1921, and as a life member of the board until his death. During his residence in South Bend, in 1908, he helped to organize the Union Trust Company and was a director and vice-president. This organization was later merged with the First National Bank.

On May 23, 1893, Mr. Hammond was married to Flora Troll of Sullivan, Ind. Mrs. Hammond died on October 15, 1944. He is survived by two children, A. J. Hammond, Jr. (Lieutenant-Commander, U. S. Naval Reserve), and Mary (Mrs. George E. Davies). For the thirty years preceding his war work he resided at Evanston, Ill., a surburb of Chicago, where the family life centered around the First Presbyterian Church and the Shawnee Country Club. He is buried at South Bend—his home when the children were young.

Mr. Hammond was elected a Member of the American Society of Civil Engineers on June 1, 1904, and an Honorary Member on October 12, 1942.

MORTIMER ELWYN COOLEY, Hon. M. Am. Soc. C. E.[1]

Died August 25, 1944

Mortimer Elwyn Cooley, the son of Albert Blake Cooley and Achsah (Griswold) Cooley, was born at Canandaigua, N. Y., on March 28, 1855. He was a younger brother of the late Lyman E. Cooley, M. Am. Soc. C. E. The first nineteen years of his life were passed at Canandaigua in the agricultural district of the Finger Lakes region. He was a product of those great twin mentors, the American farm and the rural district school.

With this background, supplemented by his secondary school work at Canandaigua Academy, he took and passed the entrance examinations for the United States Naval Academy at Annapolis, Md., and entered as a Cadet Engineer in 1874. His roommate and classmate at Annapolis, who became his lifelong friend, was the late Ira N. Hollis, for many years a professor at Harvard University in Cambridge, Mass., and later president of Worcester Polytechnic Institute at Worcester, Mass. The lives of these two friends ran in parallel courses. Inseparable in school, assigned to the *U. S. S. Quinnebaug* on graduation in 1878, they were together on an extended cruise in the Mediterranean Sea in 1879 and eventually both of them were detailed by the Navy to teaching. Both resigned from the Navy and both became men of outstanding influence in engineering education. They were lifelong cronies.

---

[1] Memoir prepared by a Committee consisting of Herbert S. Crocker and Henry E. Riggs, Past-Presidents and Hon. Members, Am. Soc. C. E.; Lewis M. Gram and Fred M. Zeder, Members, Am. Soc. C. E.; and Alfred H. White, Prof. Emeritus of Chemical Eng., Univ. of Michigan, Ann Arbor, Mich. (Past-President, Am. Inst. C. E.; Past-President, Society for the Promotion of Eng. Education.)

Following the year in Europe, Ensign Cooley spent a year aboard ship on the Atlantic Ocean and early in 1881, as a Lieutenant, was assigned to the Bureau of Steam Engineering. In the autumn of that year he was detailed by the Navy to inaugurate a course of instruction at the University of Michigan in Ann Arbor as "Professor of Steam Engineering and Iron Ship Building." He always was greatly pleased with this unique title given by the Navy to his teaching assignment although the university records indicate that officially he appeared on the payroll as professor of mechanical engineering from 1881 to 1922.

His four years in the Naval Academy together with cruises in European waters and with the Atlantic Squadron, plus his later experience with the Bureau of Steam Engineering, had changed the New York farmer's boy into a traveled, well-rounded man, who had made intimate contact with engineering problems and had secured not only a practical knowledge of steam engineering but confidence in himself. This is well illustrated by a story he has often told of his first faculty meeting at Ann Arbor. Some matter came up which required a vote of men of professorial rank only. When the ballot box came to Professor Cooley (he was then twenty-six years old), James B. Angell, then President of the University, raised the question as to whether "this young man" was entitled to vote. Before any one had a chance to discuss it, Professor Cooley rose, stated that he had been detailed by the Navy to the university as professor of steam engineering and that he considered that to be his rank, and proceeded to cast his ballot. Afterward no one ever questioned his title or rank.

An Engineering Department of very limited size and curriculum was established at the University of Michigan in 1857. In 1880, prior to the arrival of Professor Cooley, the faculty numbered three men and previous teaching had been limited to civil engineering and surveying. The total enrolment of engineering students in 1881 was 25. With the appointment of Professor Cooley the scope of the Engineering Department was extended to include courses and degrees in mechanical engineering. The first degree in mechanical engineering was given in 1883. The Department of Electrical Engineering was created in 1889 and the Department of Chemical Engineering in 1900. Thus, it is obvious that Professor Cooley can be rightfully classed as one of the pioneers in the founding of a great engineering college.

By 1895 the growth and development of curricula was such that the Regents established the College of Engineering and appointed Charles E. Greene,[2] M. Am. Soc. C. E., as the first dean. Professor Cooley became Dean of the College of Engineering in 1903 after the death of Dean Greene. In 1913 his title was changed to that of Dean of the Colleges of Engineering and Architecture. He retired in 1928 with the title of Dean Emeritus. During the twenty-four years of his administration, the departments of Architecture, Architectural Engineering, and Aeronautical Engineering were established. The total enrolment increased from 828 undergraduate and 7 graduate students in 1904 to 1,652 undergraduate and 81 graduate students in 1928.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXIV (1921), p. 849.

The significance of Dean Cooley's work at Michigan is not to be found in enrolment records, number of teachers, number of departments established, or courses offered. He clearly recognized the necessity for undergraduate education in the fundamental sciences with emphasis on a broad liberal training in the four-year course. In fact, he held that specialization in any field of engineering required a longer course or should be reserved for graduate work. Among other things he was insistent that every graduate have a reading and speaking knowledge of some foreign language. He believed that particular attention should be given to freshmen and was the founder of Michigan's mentor system. This plan has done much to help new students solve not only their problems of scholarship, but personal troubles as well.

Dean Cooley's conception of an engineering education was one of training for leadership, not only in design and construction of engineering projects, but in pure science, research, management of industrial properties, and good citizenship. It was with this vision of the engineer's function in society that he laid the foundations for the present very marked development of the College of Engineering as a center of graduate teaching and research attractive to men who have taken degrees in other engineering colleges.

His active service to the University of Michigan covered a period of forty-seven years. After retirement he resided in Ann Arbor, and maintained an office on the campus as adviser, counselor, and friend of both the faculty and the student body. Sixty-three years of his life were devoted to the service of the university as teacher, administrator, and adviser—this was his principal lifework. He left a record at the University of Michigan that will never be erased. The establishment by the Board of Regents of the Mortimer E. Cooley Foundation to

> "* * * insure the maintenance of a strong and adequate faculty for undergraduate teaching * * * to encourage and foster graduate work in Engineering * * * to encourage fundamental research in pure and applied science * * *"

will be a more lasting monument than marble or granite.

Professor Cooley resigned his commission in the Navy in 1885 but always maintained his keen interest in the service. On the outbreak of the Spanish American War in 1898 he re-entered the Navy with the rank of Chief Engineer and served first as Chief Engineer of *U. S. S. Yosemite,* and later at League Island Navy Yard, Philadelphia, Pa. He had long been interested in naval training on the Great Lakes, and from 1895 to 1911 he served as Chief Engineer Officer of the Michigan State Naval Brigade. Later, during World War I, he served as educational director of the seventy-two colleges and universities in Michigan, Wisconsin, and Illinois which comprised the Seventh District of the Students Army Training Corps.

His public service was of a widely diverse character. From 1888 to 1890 he was a member of the Board of Public Works of the City of Ann Arbor, and from 1890 to 1892 he was president of the Common Council of the city. From 1907 to 1912 he served as chairman of the Block Signal and Train Control Board of the Interstate Commerce Commission. In 1915 and 1916 he was chairman of the Board of Consulting Engineers which designed the present Belle Isle Bridge at Detroit, Mich. From 1920 to 1923 he was a member of the Advisory Council of the Joint Commission on Postal Service. In 1924 he was the Democratic nominee for United States Senator from Michigan and made a state-wide campaign for the office. He had no expectation of being elected but nevertheless received great pleasure from this campaign in which he argued that members of the engineering profession should be given greater prominence in public affairs. In 1933–1934 he served as state engineer for Michigan under the Federal Public Works Administration, becoming director in 1935. In 1934 he was appointed chairman of the Advisory Board to the Michigan State Highway Department.

Few if any citizens of Michigan have given the state more capable and varied service on commissions—with compensation consisting in large part of the satisfaction of promoting public welfare since only out-of-pocket expenses were paid. No other professional man ever won a place in the public affection and esteem of the whole state equal to that of Mortimer E. Cooley.

In the beautiful hill country of northern Michigan, State Highway No. 55 crosses the Manistee River in the Manistee National Forest over a long, high bridge which was selected as the most beautiful bridge of its type built in 1935. It was officially named the Mortimer E. Cooley Bridge and the bronze tablet at its east entrance records the high esteem in which the state held this citizen.

Throughout his life Dean Cooley was keenly interested in the advancement of the engineering profession and was active in state and national professional societies. He became a member of the Michigan Engineering Society in the early 1890's, served as its president in 1903, and was one of its first honorary members. He was vice-president of the American Society of Mechanical Engineers in 1902–1903 and president in 1919; he was made honorary member in 1928. He served as vice-president of Section D of the American Association for the Advancement of Science in 1898, as president of the Society for the Promotion of Engineering Education in 1920–1921, and as president of American Engineering Council from 1921 to 1923. He was an honorary member of the Engineering Society of Detroit, and a member of the National Association of Power Engineers and, until the time of his retirement, of the American Institute of Consulting Engineers.

During all the years that he was in active university work, Dean Cooley was called upon as a consultant in many matters. As a mechanical expert on patent litigation he was in frequent demand and testified in many cases between 1893 and 1925. He made a number of tests of water works pumping engines in Michigan and Ohio cities. He designed heating, lighting, and water plants for several of the large state hospitals and schools in Michigan.

His most outstanding work as a consultant was in the field of valuation. In 1900 the State of Michigan undertook the valuation of railroads, telephones, and other specific tax-paying properties in order to secure information to guide the legislature in the consideration of an ad valorem system of taxation. The Hon. Hazen S. Pingree, then Governor of Michigan, appointed Mortimer E Cooley appraiser and left the selection of staff wholly to him.

Prior to 1900 there had been a few water works valuations and perhaps half a dozen appraisals under the Texas stock and bond law. There was no literature on the subject of valuation. The only decision bearing on it was that in the famous case of Smyth versus Ames, which had been handed down two years earlier. There were no established principles or methods of valuation. Professor Cooley chose a staff of about one hundred engineers—the older men experienced and long in responsible charge of railroad construction and maintenance, the younger ones all graduate engineers with some experience. This was the first state-wide valuation in the United States. Definite rules of procedure were adopted. Forms were developed for the inventory of all kinds of property. Careful price studies were made. Cost of reproduction at then current price levels was adopted for the first time. Depreciation was determined by the inspection method. This valuation established precedents which were the models adopted in all subsequent state valuations and in the federal valuation of railroads. The Michigan valuation developed theories and methods which have been approved in a long line of federal and United States Supreme Court opinions in subsequent years.

The appraisal of 1900 was brought up to date in 1903 and 1905, and was followed from 1908 to 1920 by valuations of electric power and electric railway properties and gas plants for the State of Michigan—all under the direction of Mortimer E. Cooley and the staff selected by him. All this work, in this twenty-year period, was done as an engineering job, without any political interference and without the appointment of a single man on political recommendation.

During these twenty years Professor Cooley was called in as consultant by the State of Wisconsin, by Newfoundland, by Ontario (Canada), and by many cities and private corporations. One of his greatest contributions to the engineering profession was the establishment of a sound set of principles and methods upon which the valuation of utilities has since been developed.

During his busy years of university teaching and administration, public service, and private practice, many honors were conferred upon Mortimer E. Cooley. In 1885, at the time of his resignation from the Navy, the University of Michigan conferred on him the degree of Mechanical Engineer; in 1907 Michigan Agricultural College (Michigan State College of Agriculture and Applied Science at East Lansing) gave him the degree of Doctor of Laws; in 1911 the University of Nebraska at Lincoln granted him the degree of Doctor of Engineering; in 1923 Armour Institute of Technology at Chicago, Ill., conferred on him the degree of Doctor of Science; and in 1929 the University of Michigan gave him the honorary degree of Doctor of Engineering.

Sigma Xi, Tau Beta Pi, and Phi Kappa Phi honorary societies elected him to membership, and in addition he was elected to six of the chapters of the honor societies in the university by the student members. He was the recipient of the Navy Service Medal, the Detroit Naval Reserve Medal, and the Washington Award of the Western Society of Engineers. He served as Director of the American Society of Civil Engineers from 1914 to 1916.

On December 25, 1879, Mortimer Elwyn Cooley was married to Carolyn

Elizabeth Moseley. Their children were Lucy Alliance (Mrs. W. O. Houston), Hollis Moseley Cooley (Captain, U. S. Navy), Anne Elizabeth (Mrs E. C. Howe), and Margaret Achsah (Mrs. H. F. Cornwell).

The Cooley home in Ann Arbor abounded in hospitality and comfort. Scores if not hundreds of visitors to the city were cordially welcomed there. Mrs. Cooley was a lovely and highly cultured lady, greatly loved in the community, and active in church and charitable work. Her gracious welcome made any visit to her home a joy. She died on October 19, 1932, deeply mourned by a host of warm friends.

The foregoing paragraphs represent an attempt to summarize the principal facts regarding a long and busy life of service. They do not however picture the great, attractive personality that was Mortimer E. Cooley. To those who were privileged to work with him in the university for many decades his outstanding qualities were intense loyalty to the Engineering College, the desire to see it become a place where professional leadership could be developed, absolute freedom from prejudice in favor of any one department or field of professional work, the unerring ability to see the good points in young men and to sense the qualities that would make them good engineers, and complete and utter fairness to all. The task of the College of Engineering was to turn out good citizens and good engineers, leaders in their special field, and not to give a technical smattering which would qualify the graduate to hold an employee's job for life.

To those who have worked by his side in professional practice his abilities to analyze the work to be done, to plan the attack on it, to see both sides of every controversial question, and to insist upon careful analysis before reaching a conclusion were his outstanding qualities.

Mortimer E. Cooley sought the basic truth before attempting to solve any problem, engineering or educational. He always gave credit to members of his staff and never took full credit for the success of any undertaking. "There is always credit enough on a job that is well done to go around to all of those who did it" was a frequent saying of his, which always was evident in his reports.

He found time to write. His poems were real poetry. His papers on engineering education found a place in the great newspapers as well as in the technical press. His work on the Cooley genealogy of more than a thousand pages represents great research and must have taken a long time—yet he never talked much about it.

Dean Cooley's friends, neighbors, and colleagues will long remember the genial scholarly gentleman who could order the best of dinners and spin the best of yarns, whose smile was infectious, whose wit was always ready, and whose sarcasm, when occasion demanded, was biting. Those who have had the great privilege of being with him when he completely threw off the burden of work are the ones who have really seen the charming human side of this splendid gentleman.

He was a member of the Army and Navy Club of Washington, D. C., and of the Detroit and Yondotega clubs of Detroit. Those friends who have met him at any of these clubs saw him at his best with work and worry laid aside, free to discuss his many varied interests or his firm advocacy of the American way of life and of sound doctrines of politics and government.

His was a long life—full and useful. His influence will continue. His impress on the present generations of engineers has been deep and the influence of his teachings and the memory of his personality will not soon be lost. His principal monument is the great Engineering School, not alone the buildings (although he was in very large measure responsible for them), but the ideals of professional education which he did so much to establish.

Dean Cooley was elected a Member of the American Society of Civil Engineers on May 2, 1911, and an Honorary Member on October 14, 1935.

JOHN EDWIN GREINER, Hon. M. Am. Soc. C. E.[1]

Died November 15, 1942

John Edwin Greiner was born in Wilmington, Del., on February 24, 1859, the son of John and Annie (Steck) Greiner. At the age of nineteen his father moved from Ohio to Wilmington and during the Civil War served as a cavalryman in the Home Guards. Later he became a successful businessman. His mother, a native of Philadelphia, Pa., was well educated, fond of music, an accomplished pianist, and a good singer. From her Mr. Greiner inherited the fondness for music which was so evident throughout his life.

In his early childhood Mr. Greiner lived on a farm just outside of Wilmington. When young John was eight years old, his father sold the farm, and the formative years in the life of the youngster who was later to become such an eminent engineer were spent in the city of Wilmington.

His early education was obtained in the primary and secondary public schools of Wilmington, and at the age of fourteen he entered the Wilmington High School from which he was graduated in 1877. As a high school student he was interested in sports and in music, particularly in the violin which he played at both dances and concerts.

Mr. Greiner's record in high school was such that he was able to matriculate without examination at Delaware College (later the University of Delaware) at Newark, Del. At the conclusion of a three-year scientific course he was graduated in 1880 with the degree of Bachelor of Science. While in college Mr. Greiner engaged in extracurricular activities to a considerable extent—gymnastics, boxing, football, music, and dancing. He also organized the college orchestra.

Following graduation Mr. Greiner obtained a position as a draftsman in the Engineering Department of the Edge Moor Bridge Works, not far from his home in Wilmington. During the time he worked with this firm Mr. Greiner continued his studies and in 1883 he received the degree of Civil Engineer from Delaware College. In the same year he resigned from the employ of the Edge Moor Bridge Works and accepted a position as an assistant engineer with the Keystone Bridge Works in Pittsburgh, Pa. The notes in Mr. Greiner's uncompleted autobiography concerning his duties with the Keystone firm state, "The most interesting part of my work was when I assisted Mr. Thacher [the late Edwin Thacher,[2] M. Am. Soc. C. E.] (the chief engineer) in the design of the first bridge the Baltimore and Ohio Railroad Company built across the Susquehanna River at Havre de Grace [Md.]." In view of Mr. Greiner's later connection with this bridge—the present bridge of the Baltimore and Ohio Railroad Company at substantially the same location and the parallel highway bridge completed in 1940—one may comprehend why Mr. Greiner so vividly recalled his first association with a bridge spanning the Susquehanna River.

---

[1] Memoir prepared by a Committee consisting of Ezra B. Whitman, Past-President, Am. Soc. C. E., and Gustav J. Requardt and Herschel H. Allen, Members, Am. Soc. C. E.

While in Pittsburgh Mr. Greiner received an offer from the late Gustav Lindenthal,[3] Hon. M. Am. Soc. C. E., to act as resident engineer for Mr. Lindenthal during the erection of the Seventh Street Bridge across the Allegheny River. Mr. Greiner accepted the position, and during this engagement he began to evidence those qualities of originality and genius which were to make him nationally and internationally known during later years.

Upon completion of the Seventh Street Bridge in 1885, Mr. Greiner returned to Wilmington for a well-earned vacation. The vacation however was of short duration for at the end of two weeks he was employed by the Baltimore and Ohio Railroad Company as a bridge draftsman. His advancement was rapid. The following year he was made bridge inspector and in 1887 chief draftsman. In 1889 he became assistant bridge engineer.

In 1891 feeling that his work with the Baltimore and Ohio Railroad Company was rather routine and desiring broader executive responsibilities, Mr. Greiner resigned and accepted a position as designing engineer with the Philadelphia Bridge Works at Pottstown, Pa. He remained at Pottstown only two years, however, as the Baltimore and Ohio recalled him in 1893. He was then appointed bridge engineer. In later years Mr. Greiner referred to this temporary severance of his connection with the railroad company as a "furlough." Mr. Greiner remained with the Baltimore and Ohio Railroad Company for the next fifteen years. In 1899 he was promoted to engineer of bridges and buildings and in 1905 to assistant chief engineer.

In 1908 Mr. Greiner, then forty nine, faced the problem of whether to remain with the Baltimore and Ohio Railroad Company and probably become, in subsequent years, its chief engineer or whether to resign and enter consulting practice. The notes for his autobiography concerning the reasons governing his decision to resign reveal both his modesty and the firm confidence which he had in his own ability. That this confidence was shared by others is evidenced by the fact that at the farewell reception given to Mr. Greiner the late D. D. Carothers,[4] M. Am. Soc. C. E., then chief engineer of the Baltimore and Ohio Railroad Company, announced the appointment of Mr.

Greiner as consulting bridge engineer for the railroad company, a position which he held until his death.

Shortly afterward Mr. Greiner was appointed consulting engineer for the Erie Railroad Company, a relationship which continued until 1918. By 1911 the number of individual projects upon which Mr. Greiner's services were engaged had risen to more than thirty and by the end of 1916 to one hundred and eighteen. As his practice grew, Mr. Greiner added to his organization partners and associates and increased the number of the junior personnel. The work done by the firm included reports of various types in addition to complete design and supervision of construction. At the time of Mr. Greiner's death the value of the projects completed by the company was in excess of $300,000,000. Among the more important projects were eight large bridges across the Ohio River; the Soldiers and Sailors Memorial Bridge at Harrisburg, Pa.; the James River Bridge near Newport News, Va. (a structure approximately 4.5 miles long with a vertical lift span over the main channel); a concrete arch bridge over the James River at Richmond, Va.; a highway bridge approximately 2 miles in length over the Potomac River near Ludlow's Ferry, Maryland; the highway bridge across the Susquehanna River at Havre de Grace (awarded first prize by the American Institute of Steel Construction as being the most beautiful steel bridge constructed in America in 1940); the Howard Street Bridge in Baltimore, Md. (given honorable mention by the Institute); the Western Maryland Terminals in Baltimore; the Army Cantonment at Fort George G. Meade, Md.; the Marine Barracks at Jacksonville, N. C.; the Marine Air Base at Cherry Point, N. C.; and the Pennsylvania Turnpike, the four-lane toll highway extending from Carlisle, Pa., to Pittsburgh.

Mr. Greiner's great achievement was his contribution to the science of building bridges and other structures. In 1896 he ascertained that the same working stresses could be employed for both built-up tension members and annealed eyebars. Prior to Mr. Greiner's discovery, lower working stresses had been employed for built-up members. Before 1903, it was common practice to use two grades of bridge steel, mild and medium, with two sets of unit stresses. In 1901 Mr. Greiner had written, for the Baltimore and Ohio Railroad Company, specifications using a single grade of steel which he called structural steel with an average ultimate strength of 60,000 lb per sq in. These specifications were adopted as standard by the American Railway Engineering Association in 1903 and have remained standard, with modifications. In 1909 he formulated a method of classifying and rating bridges according to their load-carrying capacity. This classification was likewise adopted as standard by the American Railway Engineering Association and is standard today.

Mr. Greiner believed that an engineer should share his knowledge and discoveries with the other members of his profession. He practiced this belief by writing many articles for the publications of the various technical societies. The earliest of these was an article, published by the Engineering Society of Western Pennsylvania, describing a slide-moment diagram which Mr. Greiner had invented to facilitate the computation of train-load moments and shears.

Between 1891 and 1917 Mr. Greiner wrote nineteen articles which were published by the Society. For the article, "What is the Life of an Iron Railroad Bridge,"[5] he was awarded the Norman Medal in 1896. In 1915 the James Laurie Prize was presented to him for his paper on "Coal Piers on the Atlantic Seaboard."[6]

Mr. Greiner was a member of the following national technical societies, in addition to the Society: American Institute of Consulting Engineers, American Society for Testing Materials, American Railway Engineering Association, American Concrete Institute, and American Institute of Steel Construction. He participated actively in the affairs of these organizations, especially those of the Society, the American Railway Engineering Association, and the American Institute of Consulting Engineers. He was a Director of the Society from 1915 to 1917, and from time to time served as a member of various Society committees. For many years he was chairman of the Committee on Iron and Steel Structures of the American Railway Engineering Association. He was a charter member of the American Institute of Consulting Engineers and a member of the council from 1911 to 1914.

For years Mr. Greiner was an active member, and twice president, of the Engineers Club of Baltimore.

Mr. Greiner's services were not limited to those rendered to his employers and to the clients of his firm, nor to the professional knowledge he so willingly shared with his fellow engineers. As was to be expected of a man of his capabilities and character, he neither could nor did desire to confine his activities and energies to private engagements. At various times he served his city, his state, and his country—always with distinction. In 1904 he was appointed by the Hon. Robert M. McLane, then Mayor of Baltimore, as a member of the commission to inspect and report upon the damage done by the fire which ravaged the downtown section of Baltimore in February, 1904. Shortly thereafter Mayor McLane also appointed Mr. Greiner a member of the Commission for Revising the Building Code.

During World War I, Mr. Greiner was a member of the Council of National Defense. In 1917 he was also appointed a member of the American Advisory Commission of Railway Experts to Russia by the State Department. This commission passed on the strength and carrying capacity of the bridges on the Trans-Siberian and Russian railways. As a result of his endeavors the movement of traffic over the Russian lines was substantially increased. When he returned, Mr. Greiner received the official thanks of the State Department.

From 1920 to 1927 Mr. Greiner was chairman of the Port Development Commission of Baltimore. In 1932, after having previously served as the engineer member of the Maryland State Board of Health, he was appointed a member of the Maryland Waterfront Commission. Subsequently he became a member of the committee appointed by the Hon. William F. Broening, then Mayor of Baltimore, for the preparation of an ordinance providing for the electrification of the Pennsylvania Railroad in Baltimore.

---

[5] *Transactions*, Am. Soc. C. E., Vol. XXXIV (1895), p. 294.

[6] *Ibid.*, Vol. LXXVII (1914), p. 454.

As was natural and appropriate, various honors were bestowed upon Mr. Greiner in recognition of his achievements. In 1917, Delaware College conferred upon him the honorary degree of Doctor of Engineering. In 1932, when Mr. Greiner was elected an Honorary Member of the Society, the late Francis Lee Stuart,[7] Past-President, Am. Soc. C. E., stated in part as follows:

> "His life work has run parallel with the advancement in modern bridge building and he has been such a part of that record that it is difficult to emphasize what are his important milestones in bridge design. Through his writings from time to time he has made valuable and permanent contributions to Engineering Literature."

After summarizing the more important of Mr. Greiner's achievements, Mr. Stuart said:

> "In my forty-eight years of professional and friendly contact with him I remember many other of his milestones which have been an example to the profession in ethics and citizenship, as well as ability."

In 1937 the Johns Hopkins University in Baltimore conferred on Mr. Greiner the honorary degree of Doctor of Engineering with the following citation:

> "Distinguished designer of bridges. Originator of methods, and contributor to the practice and standards of bridge building. His replacement of obsolete railroad bridges under traffic has required a judgment and an acceptance of responsibility before, during and after such replacement that are unique in the annals of his profession. His life work has run parallel with the advancement of modern bridge building and has been an essential factor therein."

In 1941 the Union Trust Company of Maryland at a ceremony which was broadcast presented Mr. Greiner with their "Plaque of Honor." This award which is in the form of a beautiful bronze plaque is given from time to time by the Trust Company to outstanding citizens. The plaque bears the following inscription:

> "For the great building feats which he has achieved throughout America; for unselfish service rendered to his country and the world; and for the renown in the field of scientific engineering which he has brought to his home city of Baltimore."

In all phases of his long and useful life Mr. Greiner was basically constructive. To both work and recreation he brought a physical and mental energy which was the envy of many of his associates. His sense of fairness and sportsmanship was never questioned and in all his relations with others he was essentially human.

In business Mr. Greiner was a firm believer in teamwork. Under his leadership and inspiration this idea permeated through and has remained in the organization he created. He insisted that employees were working with and not for the Greiner Company. Although varied degrees of responsibility were naturally borne by different members of the organization, there were "no bosses."

---

[7] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 101 (1936), p. 1493.

Mr. Greiner had marked success in his selection of associates and key employees. In choosing them, he was guided by the following specifications, which he personally drafted. These are included not only because of their value, but also because of their applicability to Mr. Greiner.

SPECIFICATIONS FOR AN ENGINEER

"An engineer, capable of taking responsible charge in the office of a consulting engineer, should have the following qualifications—

"He should be a graduate of a university or nationally recognized engineering school, a full member of a recognized national engineering society, interested and active in the technical papers and discussions of the Society and local clubs.

"He should be studious and in touch with important engineering construction, research and progress as well as with mathematics and the mechanics of engineering.

"He should be qualified to figure stresses, make designs and estimates for any kind of engineering structure with neatness, accuracy and dispatch.

"He should have experience and the ability to direct and supervise work in office or field, and to produce prompt results.

"He should be a thorough investigator and expert reviewer of drawings, be able to make clear, concise and adequate reports, specifications, contracts, etc., and to write business letters promptly, briefly and to the point, but never forgetting business courtesy.

"He should be broad-minded enough to handle efficiently a number of jobs concurrently without excitement or confusion, and have a strong enough mind to concentrate on his work and forget his personal troubles and worries while doing so.

"He should be physically strong and healthy, sure footed, able to climb, and walk on narrow supports at elevations when required in the course of field inspection.

"He should have good sense, tact, energy, decisiveness, loyalty, courtesy, and generally a character which will inspire confidence in his ability on the part of those with whom he deals.

"He should never confuse opinions and guesses with facts, make undigested statements which may possibly mislead, violate the recognized rules of engineering ethics, or do anything by act or work which may impair the confidence of those with whom he deals.

"He should not gloss over his errors or hunt excuses for them, or show resentment when they are called to his attention, but should always bear in mind that even a small error might result in considerable expense and lead to future trouble, and each discovered blunder, whether corrected in time or not, should be considered as a lesson to be remembered.

"Finally, he should have ambition, not merely for earning more pay, or for shining by reflected light, or for holding down his present job, but for earning a national reputation, for shining by the light of his own work, and for becoming a real business asset to the firm which employs him."

To his social contacts and hours of recreation, Mr. Greiner brought those same qualities which made him so successful in his profession. As previously mentioned, he was exceedingly fond of music, and was an excellent violinist. In his earlier years, he played at almost every opportunity, both with amateurs and professionals and with and without compensation. On one occasion, in company with the late Otis E. Hovey,[8] Hon. M. Am. Soc. C. E., and the late Ralph Modjeski,[9] M. Am. Soc. C. E., he played before a group of his fellow engineers in New York during a meeting of the Society. In later years his playing was largely confined to trios, quartets, and quintets composed of his close friends. He was devoted to classical music.

For outdoor recreation, Mr. Greiner liked swimming, golf, horseback riding, and hunting—particularly the latter. As a young man whenever occasion permitted, often on the coldest days, he would swim across the Delaware River at Wilmington. His hunting included shooting moose in Canada, caribou in Newfoundland, elk and goats in the Rocky Mountains, grouse and pheasants in England and Wales, ducks and geese on the Atlantic seaboard, and wild turkeys in Maryland and the South. Like all true sportsmen, he enjoyed his hunting trips because of the comradeship of his companions, the love of the chase, and the incidents which occurred, rather than because of the game he shot. However, he was quite successful, and in his office and home hang beautiful specimens of both large game and game birds.

Mr. Greiner was never idle, and his untiring energy as well as his many and varied achievements are an inspiration and a challenge to the members of the profession to which he contributed so greatly. Of him it may be truly stated that he filled "each unforgiving minute with sixty seconds worth of distance run."

In 1886 Mr. Greiner was married to Lily F. Burchell of Berryville, Va., who died in 1930. He is survived by two daughters, Lillian Burchell (Mrs. Alexander Duncan Richardson Collie) and Gladys Houston Greiner, and two grandsons, Duncan Eric Collie and Alastair Collie. Mr. Greiner's family life was a happy one and the previously mentioned notes for his autobiography contain references to the comradeship which existed between Mrs. Greiner and himself.

Mr. Greiner was elected a Member of the American Society of Civil Engineers on June 4, 1890, and an Honorary Member on October 3, 1932.

HENRY MATSON WAITE, Hon. M. Am. Soc. C. E.[1]

DIED SEPTEMBER 1, 1944

It has been said that the careers of some men are a commentary on the times in which they live. Henry Matson Waite had such a career.

---

[8] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 108 (1943), p. 1537.

[9] For memoir, *ibid.*, Vol. 106 (1941), p. 1624.

[1] Memoir prepared by a Committee consisting of Arthur S. Tuttle, Past-President and Hon. M. Am. Soc. C. E., and William B. Poland and E. W. Clark, Members, Am. Soc. C. E.

Henry Matson Waite began his career as an engineer with a railroad company when railroads were still in the expanding stage. Later, he was engaged in the development of coal mining in the early days of that industry. Then as a city engineer and following that as one of the first city managers in the country, he typified the civic aspirations of what was still a young America. At the start of World War I, he gave up civic work to go to France with the United States Army.

Returning from the war, Henry Waite planned port developments and constructed one of the finest railroad passenger terminals in the United States. In 1933 he became Deputy Administrator of the Public Works Administration, one of the best managed government agencies set up to combat the economic depression. Later, he was identified with the experimental work of the Nation Youth Administration, with the former National Resources Planning Board in its conservation and development work, and finally with the U. S. Bureau of the Budget, as the head of the War Projects Unit.

His family background was typically American. He was born on May 15, 1869, at Toledo, Ohio, the son of Henry Selden and Ione (Brown) Waite. His maternal grandfather was Gen. Joseph W. Brown, an active military figure in early days of the State of Michigan and in the War of 1812. His great-uncle, in the same line, was Gen. Jacob Brown, one of the commanders in the Mexican War. His paternal grandfather, Morison R. Waite, was Chief Justice of the Supreme Court of the United States, and Morison Waite's father was Chief Justice of the Supreme Court of Connecticut. It was in the spirit of these great forebears that Henry Waite carried on the traditional American life.

He received his early education at the Toledo High School, and his technical training at the Massachusetts Institute of Technology (M.I.T.) in Boston. One of the school friends of Henry Waite finds it interesting to recall that, in the struggles and successes of the undergraduate (particularly in the battles on the football field where Henry was a pillar of strength who would never case trying to make the always insufficiently trained M.I.T. team able to meet its rivals), the fine traits shown in Henry Waite's later career were all evident—capacity for hard work and never giving up, gaiety, ready sympathy, the ability to make and hold friends, and the power of accomplishment.

After leaving college in 1890, Henry Waite's first engineering work was with the Cleveland, Cincinnati, Chicago and St. Louis Railway Company (later a part of the New York Central Railroad Company) as a transitman and then as engineer of maintenance of way. In 1893 he became division engineer with the Cincinnati, New Orleans and Texas Pacific Railway Company (later a part of the Southern Railway Company), and during the following fourteen years he was promoted to bridge engineer, to roadmaster, and finally to division superintendent. In 1907 he was appointed superintendent of the Seaboard Air Line Railway Company, leaving in 1909 to become vice-president and chief engineer of the Clinchfield Coal Corporation at Dante, Va., where he remained until 1912.

Until this time, Henry Waite had conformed to the usual pattern followed by a successful engineer. A major change occurred, however, in his career when, in 1912, he accepted the appointment as city engineer of Cincinnati, Ohio, under what has been termed the first "reform" administration for that city. Thus, he began, in connection with his engineering, the civic side of his life; and his interest in municipal government never lessened. This experience in public administration led to his appointment as city manager of Dayton, Ohio, in 1914, at a time when the city manager form of government was in its trial period. Henry Waite made good as city manager of Dayton and, in doing so, attained national prominence. The success of the municipal administration in Dayton promoted the city manager system in the United States. Throughout his life, Henry Waite actively advocated this type of municipal government.

With the beginning of World War I, Henry Waite resigned as city manager of Dayton and volunteered his services to the United States Army. He was commissioned a Lieutenant Colonel in the Corps of Engineers and was sent to France. There he served with the Transportation Corps, American Expeditionary Forces, under Brig.-Gen. W. W. Atterbury,[2] M. Am. Soc. C. E.—first as Deputy Director General of Transportation, then as Engineer of Construction. Later, he was promoted to the rank of Colonel and was made Assistant Deputy General of Transportation, Second American Army, Advance Zone. Finally, he was transferred to the Third Army and was a member of the American Bridgehead Commission at Koblenz, Germany. For his meritorious services, he was awarded the Distinguished Service Medal of the United States and was made an officer of the Légion d'Honneur of France.

In the spring of 1919 Colonel Waite returned to the United States and, upon his discharge from the Army, became vice-president and chief engineer of the Lord Construction Company of New York, N. Y. In 1920 he was made president of the Lord Drydock Company which formulated plans for the development of the Port of New York. After winding up the affairs of the drydock company, he entered private practice as consulting engineer in New York City.

In 1927 Colonel Waite was called to Cincinnati to become chief engineer of the Cincinnati Union Terminal Company. In that position he was responsible for organizing, planning, and building a forty-million-dollar passenger terminal—one of the outstanding undertakings of its kind in the United States. He completed the project six months ahead of the original schedule and within the estimated cost. This terminal stands as one of the greatest monuments to his vision and ability.

Following the completion of the Cincinnati terminal in 1933, Colonel Waite went to Washington, D. C., to work with a small group in devising the policies and plans for what was later to become the Public Works Administration. Subsequently, after the enactment of the National Industrial Recovery Act and the establishment of the Public Works Administration, Colonel Waite was appointed Deputy Administrator, under the Hon. Harold L. Ickes, Secretary of the Interior, and was placed in charge of the three-billion-dollar public works program which took the form of grants or loans and grants to public agencies, thus enabling the agencies to proceed with worth-while improvements. The major share of the responsibility for organizing this public works program—one of the largest ever undertaken in the United States—rested upon Colonel Waite. At this particular time, the construction industry was dormant and unemployment was prevalent among engineers. Because of Colonel Waite's energy and administrative ability, coupled with the aid of a carefully selected staff, the program was advanced rapidly and engineers quickly began to enjoy comparatively prosperous days. The outstanding service rendered by Colonel Waite in this field placed the profession under a debt of gratitude which should never be forgotten. With the program well under way, he resigned in the autumn of 1934 to direct an unemployment survey in Cincinnati for the Regional Department of Economic Security, a nongovernmental organization. He inaugurated and conducted this work and completed it in 1937.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 101 (1936), p. 1518.

In the latter part of 1937, Colonel Waite resumed his activities with the federal government as technical adviser to the National Youth Administration and as a consultant to the National Resources Committee (a predecessor of the National Resources Planning Board). For the National Youth Administration, he organized and operated the experimental project at Quoddy (near Eastport), Me., for training boys in various phases of mechanical work, and much of his time in 1937 and 1938 was spent at Quoddy. Subsequently, this project was used as a pattern for other similar schools.

After 1938 he served actively as chairman of the Chicago (Ill.) Subway Committee, which was responsible for approving the plans made by the Transportation Committee of the City of Chicago for the subway. This $56,000,000 project, for which the Public Works Administration had made a grant of $23,130,000, occupied much of Colonel Waite's time until his death.

For many years Colonel Waite had been an advocate of a national planning agency that would be primarily concerned with the physical development of the United States. While with the National Resources Committee and later while with the National Resources Planning Board, he served as chairman of the public works committees— a task which was undertaken at the request of the Hon. Franklin D. Roosevelt, President of the United States. These committees, under Colonel Waite's chairmanship, were responsible for developing procedures under which the planning, programming, and budgeting of federal public works projects could be coordinated into a unified operation, and for experimenting with methods by which state and local governments could prepare and keep up to date six-year programs of their public works activities. These latter experiments received wide publicity and were highly successful in various states and localities. Colonel Waite continued with the board until the autumn of 1940.

During 1939 and 1940, Colonel Waite also found time to serve as chairman of the Dayton and Montgomery County (Ohio) Survey for the improvement of public administration in the city and county governments.

Late in November, 1940, the Hon. Harold Smith, director of the U. S. Bureau of the Budget, requested Henry Waite to form and direct the War Projects Unit of the Bureau. Colonel Waite organized this work under the title of consultant to the Budget and head of the War Projects Unit. In this capacity he directed a field staff who surveyed and reported on the progress of government-financed war construction and, later, on the progress of the major war production programs. He was still actively engaged in this work at the time of his death.

In addition to his military honors, Colonel Waite received the honorary degree of Doctor of Laws from Miami University in Oxford, Ohio, and that of Doctor of Engineering from the University of Cincinnati. He served as vice-president of the Society in 1931–1932. Colonel Waite was a member of the Society of American Military Engineers (at one time vice-president), the International Association of City Engineers (past-president), the International Association of City Managers (one of the founders), the American Society of Municipal Engineers, the International Association of Public Works Officials, and the American Public Works Association.

On April 15, 1914, he was married to Mary Mason Brown of Lexington, Ky. Colonel Waite is survived by his widow. Any one who has ever enjoyed the hospitality of the Waite home would know the happiness which followed this union, and the inspiration Mrs. Waite always gave to Colonel Waite.

Throughout his varied and colorful career, Henry Waite brought a clear, logical mind to the solution of not only engineering but all other problems that he encountered in his lifetime. At the same time he never lost the human touch. His personality was such that, while leading men, he made them love him, as well as admire him. During his later years, he maintained a lively interest in the arts, being a lover of music, painting, and the theater. He also read widely. His life was an inspiration to all who knew him.

Colonel Waite was elected a Member of the American Society of Civil Engineers on April 1, 1914, and an Honorary Member on October 13, 1941.

EDWARD EVERETT WALL, Hon. M. Am. Soc. C. E.[1]

Died June 26, 1944

Edward Everett Wall was born at Cambridge, Saline County, Mo., on August 15, 1860. He was the son of John and Mary (Gault) Wall.

In 1833 John Wall, as a boy, was brought to Saline County. He fought in the Mexican War in Doniphan's noted regiment and then became one of the "forty niners" who went to California in a train of ox-drawn covered wagons. However, he soon returned to Cambridge and became sheriff as well as a merchant and a farmer. A little later, he became a soldier in the War Between the States. The fact that he fought on the Union side, although from a part of Missouri overwhelmingly Confederate in sympathy, is an example of the Wall family trait of independence. His son, Edward Everett, had the same characteristic of always acting as he thought right regardless of the politics of the occasion.

---

[1] Memoir prepared by a Committee consisting of Baxter L. Brown, W. J. Burton, and W. W. Horner, Members, Am. Soc. C. E.

Edward Wall attended the public schools at Cambridge and then the University of Missouri at Columbia, from which he was graduated with the degree of Civil Engineer in the class of 1884. In September of the same year he began work with the Mississippi River Commission as recorder for a gaging party at Arkansas City, Ark., remaining until April, 1885. From September, 1885, to May, 1886, he served as leveler on a preliminary survey for a "short line" railroad (never built) between St. Louis and Kansas City, Mo. During the summer of 1886, he was transitman on preliminary surveys for another railroad project which did not reach the construction stage—the Kansas, Colorado and Texas. Then, from September, 1886, to January, 1887, he was employed as assistant division engineer on the construction of the Burlington and Missouri River Railroad (later part of the Burlington Lines) in Nebraska. His next engagement took him to Wichita, Kans., where, between April and October, 1887, he served as construction engineer on the Riverside and Suburban Street Railway (6 miles) and on the Wichita and Valley Center Railroad (12 miles). In August, 1888, he first entered the service of the St. Louis Water Department as an inspector, remaining until April, 1889. From this time until February, 1890, Mr. Wall was assistant engineer for the Missouri River Commission engaged on secondary triangulation of the upper Missouri River between Fort Benton, Mont., and Bismarck, N. Dak. Returning to St. Louis in February, 1890, he became deputy city surveyor for the W. W. Penney Surveying Company, continuing until May, 1892. This ended Mr. Wall's preparation for his lifetime service to the City of St. Louis.

Beginning as second assistant engineer in the Distribution System of the St. Louis Water Department in August, 1892, Mr. Wall rose to water commissioner and finally to director of public utilities in charge of not only the water supply but the city's power plants, street and public building lighting, city markets, and the railroad deck of the Municipal Bridge over the Mississippi River.

When he was assistant water commissioner, about the time of the Louisiana Purchase Exposition of 1904, Mr. Wall introduced the first of the processes by which the muddy water of the Mississippi and Missouri rivers not only is clarified and made safe but is transformed into one of the best large city supplies in the world. Much original research was involved in this work. The first efforts were directed toward settlement of the mud, hastened by chemical treatment to promote coagulation. Although the results were almost startling when compared with the brown liquid previously furnished to St. Louisans for water, this water was still not as clear or free from bacteria as was desirable. Accordingly, after extensive studies under Mr. Wall's direction, a very large sand filtration plant was decided upon. Such a filtration plant could not have been operated successfully without preliminary settlement and chemical treatment to remove the coarser silt particles; nor was it possible to produce satisfactory water without filtration. Accordingly, the process finally adopted included preliminary settlement of the raw water, chemical treatment followed by further settlement, then sand filtration, and finally chlorination. When completed in 1915, the Chain of Rocks filtration plant was the largest in the world and the product unsurpassed. When Mr. Wall began the improvement of the St. Louis water, the St. Louis typhoid death rate was 47 per 100,000 and the general death rate was 1,711 per 100,000. The purified water supply caused these rates to drop to 15 and 1,409 per 100,000, respectively. The Chain of Rocks water plant has a daily capacity of 160 million gal.

Shortly after the successful opening and operation of the Chain of Rocks plant, studies initiated by Mr. Wall indicated that the expected normal growth of St. Louis would require more water by 1935 than could be purified by the existing facilities. Investigations were made to determine whether it would be best to plan an enlargement of the Chain of Rocks plant or to build an entirely independent plant. These studies were by no means simple, as adequate supplies of raw water were possible from any one of three rivers in the area—the Mississippi, the Missouri, or the Meramec. Based on factors which included the center of expected population and water use, the changes necessary in the primary distribution system, and the effects of a major fire or an earthquake or other occurrence which might put the Chain of Rocks plant out of service, it was decided to build an entirely new plant which would duplicate the existing capacity but would be located at Howard's Bend on the Missouri River some thirty miles above the mouth. The studies showed that the cost advantages of the location, plus the certainty that the entire water supply could scarcely be interrupted by any even remotely possible major catastrophe, outweighed the additional expense of treating the muddier Missouri River water. The Howard's Bend plant was accordingly built in 1929. This construction involved some difficult foundation work in the alluvial river bottoms, but it was completed successfully.

In 1925 while the Howard's Bend plant was under construction, Mr. Wall was promoted to director of public utilities. As director he initiated the change from gas to electricity for city lighting—a long-time contract having prevented this change earlier. In connection with this program and very characteristically, he refused the request of the mayor to make certain personnel changes in his organization for purely political reasons and resigned instead. His adherence to principle was applauded and eventually led to the downfall of the mayor. After some five years in private practice, Mr. Wall was reappointed director of public utilities when a new administration was elected. He served until 1941 when advancing years caused him to retire.

Mr. Wall was quiet, unassuming, and modest. Those privileged to know him well remember him as kindly, generous, and considerate; an ever loyal friend. He greatly enjoyed his contacts with engineers. His particular hobby was the expression of his thoughts in verse and for a considerable period of years he exchanged his "poems" with J. D. von Maur, M. Am. Soc. C. E., a former St. Louis engineer living in Canada. These verses were collected and published for private distribution locally and at the time of Mr. Wall's death had filled two volumes[2] with a third in prospect. He wrote a somewhat similar but more pretentious prose effort, "Engineers, Engineering, and Some Vagaries."[3] The scope and charm of Mr. Wall's reasoning and attitude toward life are glimpsed by some of the chapter headings: "Advantages of Not Being Too Clever," "Engineering Ethics," "General Education for the Engineer," "Helping Each Other to Help the Profession," "Human Side of Engineering," "Luck," "Musical Tramp," "One Honest Man," and "Trees."

---

[2] "Literary Productions of Two Civil Engineers," by J. D. von Maur and E. E. Wall, Locust Printing Co., St. Louis, Mo., 1940–1943.

[3] Engineers, Engineering, and Some Vagaries," by Edward E. Wall, Carter & Wilson, St. Louis, Mo., 1931.

Mr. Wall became a member of the St. Louis Engineers Club in 1889 (president in 1908). He belonged to the American Water Works Association (trustee from 1921 to 1923) and was on the standardization council in 1924–1925. He was a member of the American Public Health Association from 1915 to 1928, the American Society of Municipal Engineers from 1920 to 1927, the St. Louis Institute of Consulting Engineers (president in 1928), the St. Louis Academy of Science, the Circle Club, the Noonday Club, Tau Beta Pi fraternity, and the Masonic fraternity. In 1935 the University of Missouri conferred on him the honorary degree of Doctor of Laws.

In 1901, Mr. Wall was married to Jessie Towne of St. Louis. Mrs. Wall died in 1929 and was buried in Valhalla Cemetery at St. Louis. When Mr. Wall died, a Masonic service was held at the home and he was interred beside his wife. Many of his old-time friends served as honorary pallbearers in token of their high regard for him.

Always interested in Society affairs, Mr. Wall served as Director from 1918 to 1920 and as Vice-President in 1921 and 1922. In 1908 he was awarded the Thomas Fitch Rowland Prize for his paper on "Water Purification at St. Louis, Mo."[4]

Mr. Wall was elected a Member of the American Society of Civil Engineers on February 1, 1905, and an Honorary Member on October 10, 1938.

JEREMIAH AHERN, M. Am. Soc. C. E.[1]

Died April 19, 1944

Jeremiah Ahern was born on July 5, 1860, in Alameda County, California, near what was later called Grove Street and University Avenue in Berkeley.

Although it is not known in what year his parents, Jeremiah and Bridid (Marnen) Ahern, came to California, it can be truthfully said that he was the son of pioneers and that he grew up under pioneering conditions. Not until he was eight years old did the first continental railroad train arrive in California. In the same year, 1868, the University of California was incorporated, its site at Berkeley being within a quarter of a mile of the Ahern home.

Young Ahern was inspired by the great work of the late Theodore D. Judah,[2] M. Am. Soc. C. E., in locating and constructing the Central Pacific Railroad across the Sierra Nevada, and we know he was also familiar with the marvelous work other engineers were doing in the same mountains in storing and transporting water for use in gold mining. It was the last of the "Golden Era" in California and it was easy to foresee the unlimited opportunities open to the civil engineer in the development of the Pacific Coast.

---

[4] Transactions, Am. Soc. C. E., Vol. LX (June, 1908), p. 170.

[1] Memoir prepared by Norwood Silsbee, Assoc. M. Am. Soc. C. E., and Joseph W. Gross, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. XXXVIII (December, 1897), p. 448.

Therefore, when he was nineteen, young Ahern entered the University of California, in the Class of 1883.

Pioneering conditions still prevailed in the West. Travel was mainly by horses; Indians were not always friendly; outlaws were common; and sleeping and eating conditions outside the cities were primitive—but so strong was the appeal of the outdoor life to Jeremiah Ahern that for the twenty-five years of his active professional life he deliberately adopted it and enjoyed it.

For the first nine years after leaving college he served with the United States Geological Survey: From 1883 to 1888 as assistant topographer in California, Virginia, Alabama, and Georgia; in 1888 as topographer in charge of parties in Pennsylvania; and from 1889 to 1891 as topographer of the Powell Irrigation Survey in Montana. It was during these early years of the Geological Survey, organized in 1879 under Maj. John Wesley Powell, of Colorado River fame, that Mr. Ahern won the lasting friendship of so many of the engineers who afterward became noted in government work.

In 1892 Mr. Ahern left government employ and became associated with McCray Brothers, civil and hydraulic engineers of San Francisco, Calif. During the three years with this firm, he acted as assistant engineer on the South Gila Canal Project, in Arizona, making surveys and plans for a reservoir, canals, wagon roads, and irrigation system; as assistant engineer on location of a proposed railroad from Monterey Bay to Fresno, Calif., over the Coast Ranges; and in preparation of plans and estimates for irrigation storage dams on the San Luis Rey River, in California.

Returning to the United States Geological Survey in 1895, for the next three years Mr. Ahern was in charge of surveys in Indian Territory, which had been opened to settlement by the white man a few years earlier. From 1899 to 1901, he was in charge of topographic survey parties in Utah and Arizona; and in 1901 and 1902, as hydrographer, he was in charge of hydraulic investigations on the Gila and Salt rivers, in Arizona, and on the Colorado River between Needles, Calif., and Yuma, Ariz. The party on the Colorado River survey included the late J. B. Lippincott,[3] Hon. M. Am. Soc. C. E., and W. B. Clapp,[4] M. Am. Soc. C. E. Twenty-seven miles per day for eleven days were covered, using a specially designed flat-bottomed boat equipped with a sail. Mr. Ahern's story of the early history of the Colorado River was published in the "First Report of the U. S. Reclamation Service."[5]

One of the six large proposed irrigation projects selected for study when the Bureau of Reclamation of the U. S. Department of the Interior was organized in 1902 was the Uncompahgre Valley, in Colorado. Water from the Uncompahgre River was insufficient to irrigate the 175,000 acres of irrigable land in the valley and it was proposed to supplement the supply by diversion of 1,200 cu ft per sec from the Gunnison River (Colorado), running parallel in a deep gorge twenty miles distant. Under Mr. Ahern, the necessary topographic surveys for the project were completed in 1901, including a survey of the "Grand Canyon of the Gunnison," as it was named by the Hayden Survey. That portion of the Gunnison from which the seven-mile tunnel was to start had never been explored, and the gorge was so spectacular that the survey, and the ultimate rescue of some of the party, attracted nation-wide attention.

[3] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 108 (1943), p. 1543.

[4] For memoir, *ibid.*, Vol. LXXV (December, 1912), p. 1148.

[5] "First Annual Report of the Reclamation Service, from June 17 to December 1, 1902," pp. 112, 121.

The new Reclamation Service, under its chief engineer, the late F. H. Newell,[6] M. Am. Soc. C. E., attracted many engineers from the Geological Survey, among them being Jeremiah Ahern. His first job, that of supervising investigations for the DeSmet Project, in Wyoming, was so successfully executed that in 1903 he was placed in charge of investigations for the Shoshone Project, previously promoted by Col. W. F. Cody ("Buffalo Bill").

This project, also in Wyoming, originally provided for the construction of a storage reservoir on the Shoshone River and the irrigation of 125,000 acres of land. In 1904 Mr. Ahern's plans were approved, $2,250,000 was appropriated by the government for construction, and Mr. Ahern was appointed project engineer.

The Shoshone Dam was the first high concrete dam constructed by the Reclamation Service. The late H. N. Savage,[7] M. Am. Soc. C. E., was in charge of design. The dam is of arch design, 328 ft maximum height, 200 ft crest length, 10 ft wide on top, and 108 ft thick at the base. It contains only 78,600 cu yd of concrete, has spillway capacity for 30,000 cu ft per sec, and stores 456,600 acre-ft of water.

Mr. Ahern continued on this project until its successful completion in 1908, when he resigned from government service and returned to California. There he purchased a ranch near Dixon and engaged in the private practice of his profession for the next thirty-two years.

While building the Shoshone Project, Mr. Ahern became acquainted with his future wife, Julia Bessie Lane, whose sister, Dr. Frances Lane, had a hospital in Cody, Wyo. They were married in Denver, Colo., in 1910.

Both Mr. and Mrs. Ahern were seriously injured in an automobile accident in 1941. Mrs. Ahern passed away in the Woodland Clinic (Woodland, Calif.) six weeks later. Mr. Ahern eventually recovered but age was against him and on April 19, 1944, he died of heart trouble in the Dixon Hospital. He was buried from St. Michael's Catholic Church.

Members of Sacramento Section first became acquainted with Mr. Ahern some five years after the formation of the Section, when he called the Section's attention to the entire lack of public recognition given to Mr. Judah,[2] original promoter, locator, and first chief engineer of the first transcontinental railroad. Much of the publicity since given to Mr. Judah, and the erection in 1930 of a memorial to him on the grounds of the Sacramento Depot of the Southern Pacific Railroad by employees of that company, can be traced directly to Mr. Ahern's interest in the great engineer.

---

[6] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 98 (1933), p. 1597.

[7] For memoir, *ibid.*, Vol. 103 (1938), p. 1873.

For many years Mr. Ahern did practically all the land surveying in northern Solano and southern Yolo counties and acted as consulting engineer on reclamation and irrigation problems. His intimate knowledge of the entire West and his broad business and professional experience caused him to be looked upon as an outstanding leader in the community and his opinions on public matters to be highly regarded.

As a local business friend expressed it: "He supported every activity which would benefit the community and gave generously to his church and to all worth-while charities. His neighbors were all fond of him, and his passing was a distinct loss to the community."

Mr. Ahern became a Life Member of the Society and of the Sacramento Section in 1938, being the Section's senior member in age and in length of Society membership. He was also a member of the Archæological Institute of America.

It was while he was in charge of the Shoshone Project that Mr. Ahern applied for membership in the Society, and the list of his references shows not only his standing among engineers at the time but the quality of his close friends. They were: Arthur P. Davis,[8] Past-President, Am. Soc. C. E., C. H. Fitch, J. B. Lippincott,[3] Frederick H. Newell,[6] William D. Pickett,[9] Hon. M. Am. Soc. C. E., J. H. Quinton, M. Am. Soc. C. E., and Herbert M. Wilson.

Mr. Ahern was elected a Member of the American Society of Civil Engineers on May 4, 1904.

JAMES PENNELL ANDERSON, M. Am. Soc. C. E.[1]

Died April 15, 1944

James Pennell Anderson, the son of William Edward and Mary (Wilson) Anderson, was born in Franklin, Williamson County, Tenn., on December 22, 1888. He was educated at Battle Ground Academy in Franklin, and at Branham and Hughes Junior College in Spring Hill, Maury County, Tenn.

His first engineering work was for the Louisville and Nashville Railroad Company in Nashville, Tenn., as a rodman in 1909 and later as instrumentman in Nashville and also in Montgomery, Ala. He entered the service of the Nashville, Chattanooga and St. Louis Railway in 1915 as assistant engineer. Later he was transferred to the Atlanta Division, as assistant division engineer, and was promoted to division engineer on January 1, 1926, which position he held until April 1, 1944, when he was appointed to the newly created position of engineer, maintenance of way and structures, for the entire system. He had assumed his new duties just prior to his death. He was in full charge of maintenance of way for the entire railroad with particular emphasis on roadway and track—a recognition of his outstanding maintenance work on the Atlanta Division.

---

[8] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 100 (1935), p. 1582.

[9] For memoir, *ibid.*, Vol. LXXXI (December, 1917), p. 1671.

[1] Memoir prepared by a Committee of the Georgia Section consisting of C. A. Smith, J. H. Johnston, Members, Am. Soc. C. E., and J. A. Higgs, Jr., Assoc. M. Am. Soc. C. E.

The Atlanta Division is that part of the Nashville, Chattanooga and St. Louis Railway between Atlanta, Ga., and Chattanooga, Tenn., known as the Western and Atlantic Railroad of the State of Georgia, operated under a long-term lease from the state. It is probable that the Western and Atlantic is one of the crookedest trunk-line railroads in the United States, having a curvature that averages a little more than 90° to the mile. The terrain is mountainous and the line crosses many streams, necessitating bridge structures of varied designs and lengths. Almost immediately upon taking charge, Mr. Anderson made a thorough study of the conditions on this division, particularly alinement details. The data, from which the tabular functions were calculated, were worked out by Mr. Anderson for each curve as the center line was rerun, permanent monuments were established to mark ends of spirals, points of full elevation were fixed, rate of runoff was determined, and superelevation was computed. Since there are 316 curves in 137 miles, the magnitude of this job is better appreciated. So efficiently was this work done, and line and surface constantly maintained, that the smooth movement of trains passing around the curves has been a matter of favorable comment from railway officials of other lines after riding over the Western and Atlantic Railroad.

It is a generally recognized fact that more trains are handled over the line between Atlanta and Chattanooga than on any other single-track trunk-line railroad in the United States. In addition to its own business, the Nashville, Chattanooga and St. Louis Railway handles the trains of the Atlanta-Cincinnati Line of the Louisville and Nashville Railroad Company, over the 47 miles between Atlanta and Cartersville, Ga. Because of World War II the business of both railroads has been extremely heavy, severely taxing the operating officials to handle it promptly and efficiently. In 1943 and 1944 the Nashville, Chattanooga and St. Louis Railway installed centralized traffic control over this section which has greatly facilitated operations. The installation of this centralized traffic control was under the general supervision of Mr. Anderson.

It is the well-considered judgment of engineers of long experience in track maintenance who, with Mr. Anderson, made many inspections of the Western and Atlantic Railroad, that it has been maintained in a condition that compares favorably with that of the best railroads in the United States.

On June 23, 1915, Mr. Anderson was married to Roberta Reeves, of Montgomery, who, with a son, William Reeves, survives him. Also surviving are three sisters, Alma (Mrs. J. G. Lindeman), Mary (Mrs. A. H. Thomas), and Helen (Mrs. Clark A. Bean); and two brothers, William O. Anderson and R. Gordon Anderson.

Mr. Anderson was a charter member of Cascade Methodist Church of Atlanta, served as chairman of the Board of Trustees and the Board of Stewards, and was an active member of this church until his death. He was a Christian in his daily conduct. In dealing with the men in his department he was a strict disciplinarian, but was absolutely fair and just. He had the respect, confidence, and affection of all of them down to the last section hand.

He was highly regarded not only by his own men, but by men in other departments of the Atlanta Division. He was particularly interested in accident prevention work, and his successful handling of the Safety Department on his division repeatedly won the system banner for low accident record. He was a member of the American Railway Engineering Association.

Mr. Anderson was elected a Member of the American Society of Civil Engineers on December 28, 1931.

EDGAR ALCANDER BAYLEY, M. Am. Soc. C. E.[1]

Died November 8, 1943

Edgar Alcander Bayley was born at Petaluma, Calif., on September 19, 1877. He was the son of Alcander Alonzo and Bertha (Cooper) Bayley. He received his early education in the public school system of Los Angeles (Calif.), after which he attended Throop Polytechnic Institute (California Institute of Technology) at Pasadena for two years. He then entered the law school of the University of Southern California in Los Angeles, receiving the degree of Bachelor of Laws.

From 1901 until 1905 he worked in various engineering capacities for local electric and steam railway systems. From 1905 to 1910 he was locating and division engineer for the Los Angeles Aqueduct, making the preliminary and final locations of more than half the total length of 235 miles. Much of this work was done in difficult mountainous and desert country.

During 1910 he became assistant engineer of the San Pedro, Los Angeles and Salt Lake Railroad Company (later the Union Pacific Railroad Company), on location surveys in the State of Nevada. From 1911 to 1923, Mr. Bayley was assistant engineer for the Bureau of Water Works and Supply of the City of Los Angeles, in charge of field surveys, location, hydraulic design, and topographic mapping in connection with building the distribution system and terminal storage facilities for the Los Angeles Aqueduct. This work involved the construction of many reservoirs and large pipe lines.

From 1923 to 1930 Mr. Bayley was in charge of preliminary location, mapping, water right studies, and hydrographic studies for the new aqueduct from the Colorado River to Los Angeles. (This aqueduct has been finished and is operated by the Metropolitan Water District of Southern California.) On this project, it was necessary to map 25,000 sq miles of rough desert country and to prepare locations and estimates of all possible routes for the aqueduct. During the progress of the work as many as forty plane table and triangulation survey parties were in the field, and approximately sixty draftsmen and computers were in the Los Angeles and Beaumont (Calif.) offices. The territory covered extended from Los Angeles to the Colorado River on the east, to Las Vegas, Nev., on the north, and the Mexican border on the south. The cost of the completed aqueduct was about $225,000,000.

---

[1] Memoir prepared by Ralph R. Proctor, M. Am. Soc. C. E.

During 1930 Mr. Bayley was assigned similar duties in connection with an extension of the Los Angeles Aqueduct northward into the Mono Basin. He prepared maps, estimates, etc., for two large reservoirs, with a tunnel, 11.3 miles long, and several miles of concrete conduit. The construction, land, and water right costs of this project were $20,000,000. This work was completed in 1937 and Mr. Bayley returned to the Los Angeles office to prepare studies on additional construction required for the joint use of the Los Angeles Aqueduct and the Colorado River Aqueduct in connection with the extended demand for water by the rapidly growing City of Los Angeles.

Mr. Bayley was widely known as an authority on methods of extending triangulation controls and precise levels into almost unexplored desert regions. He was particularly well versed in methods for locating conduits, tunnels, and steel pipe lines in combination to secure the most economical cost. Since he was deeply interested in financial studies, he assisted in selecting investments for the pension plan for the employees of the Department of Water and Power that was put into effect a few years prior to his death. An expert photographer, during the course of his work in remote regions he secured many outstanding photographs.

On October 27, 1903, Mr. Bayley was married to Grace Winifred Davis. He is survived by his widow and one daughter, Edith Winifred Bayley.

For many years Mr. Bayley was a member of the University Club of Los Angeles, and also was one of the founders of the Engineers Club of Los Angeles.

Mr. Bayley was elected a Member of the American Society of Civil Engineers on December 31, 1913.

PAUL LEONARD BEAN, M. Am. Soc. C. E.[1]

DIED JANUARY 29, 1944

Paul Leonard Bean of Auburn, Me., agent and engineer of the Union Water Power Company, the Androscoggin Reservoir Company, and the Union Electric Company of Lewiston, Me., from January, 1924, until his sudden death, was born at Saco, Me., on August 28, 1881. His parents were Joel and Ida Ellen (Hanson) Bean. He was educated at Thornton Academy, in Saco, and at the University of Maine, in Orono. In 1904 he was awarded the degree of Bachelor of Science in Civil Engineering and, in 1910, the degree of Civil Engineer, by the college of engineering of the university. Except for the first two years after graduation, when he was employed as a computer on special street railway work for William Wharton, Jr., and Company of Philadelphia, Pa., and as a draftsman for the Phoenix Bridge Company of Phoenixville, Pa., his entire life was spent in Maine.

---

[1] Memoir prepared by Stanley B. Attwood, City Editor, Lewiston Daily Sun, Lewiston, Me.

He returned to the University of Maine in 1907 as an instructor in civil engineering, and was promoted to assistant professor in 1909 and associate professor in 1912. During the latter year he became associated with Harold S. Boardman, M. Am. Soc. C. E., later president of the university, in the engineering firm of Boardman and Bean.

In 1915 he was appointed chief engineer of the Maine Public Utilities Commission. He organized its engineering department, had responsible charge of stream gagings and of valuation of utilities, and compiled service standards for gas and electric utilities. Other work under his direction included grade crossing elimination; bridge investigation, including condemnation, design, and repair of structures; and inspection of dams.

Mr. Bean was in sole charge of a complete water power and storage survey, covering legal, engineering, and administrative phases, presented to the Maine Legislature in 1918.

He became associated in 1919 with the late Walter H. Sawyer,[2] M. Am. Soc. C. E., of Lewiston in the construction and hydraulic engineering firm of Sawyer and Bean, the firm continuing until Mr. Sawyer's death in 1924. He then succeeded Mr. Sawyer as agent of the three companies—Union Water Power Company, Androscoggin Reservoir Company, and Union Electric Power Company—owning and operating power on the Androscoggin River and the storage reservoirs at its headwaters (the Rangeley Lakes and Aziscohos or Sawyer Lake which was created by a dam on the Magalloway River, a tributary of the Androscoggin River). In this position he was in charge of the operation of the three companies and of the design, construction, and maintenance of their facilities. The Androscoggin River has a total length of 173 miles with a drainage area above Lewiston of 2,890 sq miles and a power development of about 25,000 hp. Its storage reservoirs have a capacity of 30,000,000,000 cu ft.

It has been claimed no river in the United States of comparable size is more completely developed for storage and power. The several dams—at Upper Dam, Middle Dam, Pond-in-the-River, Rumford, Livermore, and Lewiston in Maine and Pontoocook, Errol, Berlin, and Gorham in New Hampshire—have served not only their primary purposes but have proved entirely effective in flood control except in March, 1936, when the valley was swept by the highest water on record. Until that year a flow of 60,000 to 75,000 cu ft per sec was considered exceptional. The 1936 flood is estimated to have exceeded 200,000 cu ft per sec, although means of measurement were lacking. This flood resulted from a snow cover that was heavy but not of unusual depth, plus the unprecedented combination of heavy rain and temperatures around 55° at many upriver points in mid-March. During the flood, Mr. Bean refused to leave his office since an uninterrupted flow of reports from control stations gave him a good perspective of the entire area which he felt he could better retain without a personal inspection. A hospital bed was moved to his office and, until conditions approached normal, he was never more than a few feet from a telephone.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 88 (1925), p. 1437.

During the flood period his office was besieged by property owners; by town officers from Berlin, N. H., to Lewiston and from the downriver towns of Lisbon, Lisbon Falls, Pejepscot, and Brunswick, Me.; by the Portland office of the U. S. Weather Bureau in frequent consultations; by the newspapers; and by the general public. Mr. Bean insisted all information be given out as promptly as possible, and his unfailing courtesy in this emergency was acknowledged by public officials concerned with safety measures in the flood area.

Mr. Bean's principal attributes were integrity, frankness, determination, and unselfishness. His avocations were fishing, home gardening, and football —first as a player of all-Maine caliber at the university and later as a spectator at state series games.

One of the pioneers in snow measurement as a factor in control of river flow, he applied himself in later years to the study of meteorology, forestry, soils, and kindred subjects bearing on water storage. Perhaps no one had a more thorough knowledge of Maine topography. Mr. Bean's work in design and construction of bridges and dams, location and design of water utilities, and appraisals of various other engineering works took him to all parts of the state and eastern New Hampshire. He was intensely interested in having the United States Geological Survey complete the quadrangle mapping of Maine, still about 25% unfinished, contending that accurate maps were the first essential in any plan to develop the great wild land area of the state.

When stricken fatally ill, he had begun plans to draw a relief map of the Androscoggin watershed and to write a history of the development of the Androscoggin River, particularly as it pertained to the growth of industry through generation and distribution of hydroelectric power. In addition to a large technical library, he had acquired several hundred volumes dealing with Maine.

Mr. Bean was a consultant for the Lacroix Industries of Canada. He served frequently as an adviser to various city departments of Lewiston and Auburn and to the Auburn water and sewer districts. Although a resident of Auburn, he was named to the committee in charge of design and construction of Lewiston High School and of the west wing of the Central Maine General Hospital of Lewiston, of which he had been trustee for many years. He was a director of the Androscoggin County Savings Bank of Lewiston, a former trustee of the Auburn Public Library and the Lewiston Building and Loan Association, and for thirteen years a trustee of the Elm Street Universalist Church of Auburn. He was a member of Alpha Tau Omega fraternity, of the Masons and Knights Templar, and of Kora Temple of the Mystic Shrine.

Mr. Bean was a member of the Boston Society of Engineers, a former president of the Maine Association of Engineers, and a member of the Maine State Board of Registration for Professional Engineers and that organization's examining board.

On December 24, 1907, he was married to Delia Webster of Orono. He is survived by his widow; two sons, Paul Webster, Major, Infantry, U. S. Army, and Ralph Leonard, Private First Class, Infantry, U. S. Army; and three brothers, Roger J., Ralph N., and Philip H.

Mr. Bean was elected an Associate Member of the American Society of Civil Engineers on September 2, 1914, and a Member on December 15, 1924.

JAMES WALLACE BEARDSLEY, M. Am. Soc. C. E.[1]

DIED MAY 15, 1944

James Wallace Beardsley, the son of William Hurd and Catherine Tremper (Phillips) Beardsley, was born on September 11, 1860, in Coventry, Chenango County, N. Y. After completing the classical course at the State Normal School at Cortland, N. Y., in 1884, he entered Cornell University, in Ithaca, N. Y., receiving the degree of Civil Engineer in 1891.

During the summer of 1890, Mr. Beardsley served as assistant city engineer of Binghamton, N. Y. His first engagement after graduation was with the City of Newton, Mass., as assistant engineer (September, 1891, to September, 1892) on design and inspection of sewer construction. For the following six years (September, 1892, to August, 1898), he was employed by The Sanitary District of Chicago (Ill.) on the drainage canal—an outstanding engineering project of that period. After promotions from time to time, Mr. Beardsley was given charge of the Lemont-Lockport Division of the canal. His work included heavy earth and rock excavation and the construction of massive retaining walls, foundations for the beartrap dam, bridge foundations, and superstructures at Lockport, Ill.

When this project was completed in 1898, Mr. Beardsley was engaged until October, 1899, by the United States Board of Engineers on Deep Waterways, as assistant engineer. He was placed in charge of the surveys, designs, and estimates of cost for a ship canal (St. Lawrence River route) to connect the Great Lakes with the Atlantic Ocean—including water-power development at locks and dams. From 1900 to 1902 he was surveyor with the United States Corps of Engineers in Milwaukee, Wis., and Detroit, Mich. (Fox River surveys and Sand Beach harbor of refuge designs).

In July, 1902, Mr. Beardsley was commissioned as consulting engineer to the Philippine Commission, by the late Hon. William Howard Taft, then Governor General of the Philippine Islands. When the Bureau of Engineering was organized, he became its chief. In 1905 he was made Director of Public Works of the Philippines and he inaugurated extensive programs for good roads, public water supplies, sewerage, and general sanitation. In 1908 he was commissioned to investigate irrigation in Java, Burma, India, and Egypt, reporting his findings to the government of the Philippines.

On his return to the United States in 1909, he made investigations and reports on several irrigation projects in Oregon, Idaho, Washington, Montana, and Colorado for J. G. White and Company. However, he could not long resist the urge of foreign soil, and in July, 1910, Mr. Beardsley accepted the position of chief engineer of the Puerto Rico Irrigation Service. The extensive irrigation systems designed and constructed under his direction during the succeeding six years included: Earth dams of semihydraulic fill and rolled earth embankment with crest heights of 110 and 135 ft; concrete dams of the Ambursen type with crest heights of 65 and 115 ft above the river bed; aqueducts and tunnels; highway bridges; and an hydroelectric plant with a head of 760 ft. Because of the failure and inability of local contractors to progress satisfactorily, most of these projects were constructed by the Puerto Rico Irrigation Service under Mr. Beardsley's personal direction.

---

[1] Memoir prepared by Glenn D. Holmes, M. Am. Soc. C. E.

After completion of the Puerto Rico work in August, 1916, he made a number of investigations and reports on irrigation and power projects in the western states. In March, 1918, he accepted employment as consulting engineer in the Inspection Division, U. S. Ordnance, at Washington, D. C.

From 1918 to 1920, Mr. Beardsley was assistant chief engineer of the Grand Canal Improvement Board of the Chinese Government, on surveys and designs for improvement of the Grand Canal, especially at the crossing of the Yellow River. Problems in connection with silting of streams and reservoirs were of unusual significance and required special investigation and study. When he had completed a report on this work, Mr. Beardsley was appointed chief engineer and engineer member of the Central Highway Commission of the Republic of Panama. During 1920 and 1921, under his supervision, a general highway policy was adopted, plans were prepared, and a contract was executed for the construction of 270 km (168 miles) of highways—an integral part of the intercontinental highway of the provinces. In addition, concrete and bituminous concrete roads were built near the City of Panama.

In October, 1921, Mr. Beardsley returned to the United States and was engaged in private consulting work until August, 1926. During the latter part of this period, he very graciously consented to assist the writer in the review and the preparation of a report on Onondaga Creek flood prevention, for the City of Syracuse, N. Y. This association was mutually pleasing and agreeable since it meant the revival of an old friendship between the "Chief" and one of his "boys," which began on the Deep Waterways Project in 1898.

This pleasant relationship was interrupted by an urgent request for Mr. Beardsley to become consulting engineer of the Public Works Bureau for the Dominican Republic. He accepted the position and directed the investigations, surveys, and designs for the improvement of the harbors of Santo Domingo, Puerta Plata, and Macoris. After three years of strenuous endeavor he returned to Syracuse in August, 1929, to engage again in private practice. During his many years of foreign service, Mr. Beardsley had an opportunity to explore remote and interesting places. Curios, works of art, tapestries, and jade and ivory carvings were included in his collection of mementoes. One hobby, photography, filled many albums with a record of his engineering accomplishments and observations. The albums are arranged according to subject matter—bridges, dams, monuments, irrigation, methods of transportation, and habits and costumes of various races—particularly throughout the Orient. Mr. Beardsley also collected postage stamps. Only by inquiry or after long acquaintance would one hear stories of his experiences or be shown some of these interesting collections, for Mr. Beardsley was more than unassuming and reticent regarding personal accomplishments.

Mr. Beardsley was a man of extremely high ideals. He possessed those qualities of sound reasoning, good judgment, and executive ability which particularly qualified him to be engineer, commissioner, and administrator of many large and important projects.

Mr. Beardsley was a member of the Western Society of Engineers, The Chinese and American Engineering Society, and the Technology Club of Syracuse (honorary member and past-president). For many years he belonged to the Cosmos Club of Washington, D. C.

On September 7, 1893, in Xenia, Ohio, he was married to Ellen Jane Pearne. He is survived by his widow; by a son, Wallace P. Beardsley; and by three grandsons.

Mr. Beardsley was elected a Member of the American Society of Civil Engineers on December 4, 1901.

RALPH NORMAN BEGIEN, M. Am. Soc. C. E.[1]

DIED FEBRUARY 27, 1944

Ralph Norman Begien was born on March 15, 1875, in Somerville, Mass., the son of Henry Martin and Louise Florence (Thayer) Begien, of French Huguenot and old New England stock. While he was still a child, his family moved to Medford, Mass., where he received his elementary and high school education. He attended Harvard University at Cambridge, Mass., for two years, devoting most of his time and interest to mathematics and languages, and excelling in the former.

On December 11, 1900, he was married to Ida Davenport Rozzell, of Washington, D. C. He is survived by his widow; two sons, Ralph and John; and a daughter, Jeanne.

In 1897 Mr. Begien began his professional career by joining a group of young engineers under Francis Lee Stuart,[2] Past-President, Am. Soc. C. E., on surveys for the United States Nicaraguan Canal Commission and the Isthmian Canal Commission. He worked as instrumentman, draftsman, and junior assistant engineer. In 1900 he was assistant engineer in charge of corps on preliminary surveys and location for the Guayaquil and Quito Railroad in Ecuador, South America.

He was employed in December, 1900, by the United States Government, as assistant engineer in the Engineering Department of the District of

---

[1] Memoir prepared by G. D. Brooke, E. M. Hastings, and J. E. Teal, Members, Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 101 (1936), p. 1493.

Columbia, under the Surveyor General's Office. In 1902 he resigned and returned to railroad work, this time with the Baltimore and Ohio Railroad Company, as assistant engineer (again under Mr. Stuart, who was at that time engineer of surveys for the Baltimore and Ohio). He was assigned to the study and location of various new lines, including a low-grade line from the Fairmont coal fields of West Virginia to tidewater, and had an important part in the development of a comprehensive plan of trunk-line improvements.

During the following years Mr. Begien held various positions in the Engineering, Maintenance of Way, and Operating departments of the Baltimore and Ohio Railroad Company:

Engineering Department—Draftsman, 1903–1904; assistant engineer in charge of corps on surveys for trunk-line improvements and assistant engineer at headquarters, Baltimore, Md., on special engineering investigations, 1904–1909.

Maintenance of Way Department.—Division engineer, Philadelphia Division, and acting engineer, maintenance of way, main line system, 1909–1910; assistant to chief engineer, system, 1910.

Operating Department.—Assistant to general manager, eastern lines, and assistant to third vice-president, system, in charge of operating efficiency work, 1910–1912; assistant general superintendent, main line system, 1912–1913; general superintendent, Baltimore and Ohio Southwestern Railroad Company (Baltimore and Ohio Railroad Company, successor) at Cincinnati, Ohio, in general charge of operating, engineering, maintenance of way, and equipment, 1913–1916.

Engineering Department.—Chief engineer, Baltimore and Ohio System, and Cincinnati, Hamilton and Dayton Railway Company under receivers, 1916–1917.

Operating Department.—General manager, eastern lines, Baltimore and Ohio, in general charge of operation, engineering, maintenance of way, and equipment, 1917–1918; assistant to federal manager, United States Railroad Administration, in charge of operating and engineering of the Baltimore and Ohio (eastern lines), Western Maryland Railway Company, Cumberland Valley Railroad Company, Cumberland and Pennsylvania Railroad Company, Coal and Coke Railway Company, and Wheeling Terminal Railway Company, 1918–1919; federal manager, United States Railroad Administration, in general charge of operation, traffic, engineering, maintenance of way and equipment of Baltimore and Ohio (western lines), Dayton and Union Railroad Company, and Dayton Union Railway Company, 1919–1920; general manager, Baltimore and Ohio (western lines), Dayton and Union Railroad Company, Dayton Union Railway Company, Sandy Valley and Elkhorn Railway Company, and Long Fork Railway Company, 1919–1923.

From 1903 to 1906, while assistant engineer for the Baltimore and Ohio, Mr. Begien, because of his seemingly unlimited capacity for work, established enviable records for rapid surveys in running location lines through mountainous territory in West Virginia. This he was able to do by utilizing available maps of the United States Geological Survey and because of his practical skill in reconnaissance methods. Each night he would spend some time in recording and plotting the notes of the day's work, preparing paper locations, and planning the work for the following day. His high quality of leadership was further evidenced in his personal direction of field parties, and he was the equal of any man on the party in the performance of physical tasks, often using this ability to relieve men, temporarily, who were fatigued or needed elsewhere.

While he was assistant to the general manager of the Baltimore and Ohio, Mr. Begien made an extensive study of railway operating efficiency. He established an Operating Statistical Bureau and organized methods of competition between operating divisions, comparing their operating performance on properly equated efficiency units. A number of young engineers were under his direction, who, after being trained in the use of practical statistics, put into effect the train load formula and adjusted tonnage factor for loading freight trains, which Mr. Begien had developed as chairman of the Committee on Economics of Railway Location of the American Railway Engineering Association. The operating results obtained by the use of these methods were notable and contributed to Mr. Begien's prominence as an operating officer.

Mr. Begien's extensive experience in railway engineering and operation acquired during his more than twenty years with the Baltimore and Ohio Railroad Company and his association with prominently capable railway engineering and operating men rounded out the development of an unusually active, aggressive, and prolific mind. When federal control of railroads ended in 1920, Mr. Begien was well known as a railroad man of ability and vision, with a progressive attitude toward the relations of labor and management.

On June 1, 1923, Mr. Begien became vice-president of the Chesapeake and Ohio Railway Company and Hocking Valley Railway Company and was placed in general charge of maintenance and operation. In May, 1930, when the Hocking Valley was consolidated with the Chesapeake and Ohio, he continued as vice-president in charge of engineering and related activities. On July 1, 1932, due to declining health, he was appointed vice-president—advisory.

During his association with the Chesapeake and Ohio and under his general direction, a broad program of maintenance rehabilitation and additions and betterments, including the development of the Presque Isle Coal and Ore Docks, was completed. In the decade ending in 1932, the Chesapeake and Ohio expanded its properties by acquisition and construction—595 miles of road, 287 miles of second, third, and fourth main tracks, and 789 miles of yard and industrial tracks. The work included a 65-mile, double-track, low-grade railway, connecting the trackage of the Chesapeake and Ohio and the Hocking Valley, constructed in the remarkably short time of ten months. This was indeed a fine engineering achievement. Mr. Begien was retired from active service with the Chesapeake and Ohio Railway Company on May 1, 1938.

In his younger days, Mr. Begien was quite athletic, indulging in tennis and baseball, and later in golf. He was a lifelong baseball fan. He enjoyed a vacation spent at a mountain resort, and, being a good sailor, was particularly fond of a long sea voyage. His abilities were diversified. He could run a lathe in a machine shop and write an excellent engineering report. He was a proficient and rapid draftsman, a capable locating engineer, and a mathematical expert.

Of a sociable nature, kindly and considerate, with a cheerful and optimistic disposition, he was well regarded by all who knew him, and his associates soon became his staunch friends. The possessor of an analytical and ingenious mind, with unusual clarity of vision, Mr. Begien had original and broad ideas on many phases of location and operation. He was zealous in his devotion to duty, possessed intense energy and a high degree of personal efficiency. His absorbing interest—a love for his work—made him an effective executive and an acknowledged leader in the transportation field.

He applied his thorough knowledge of railway engineering and operation and his broad experience acquired in the course of his railroad career effectively to devise improved methods and to promote efficiency in railway practices. He advocated a definite line of authority which permitted the individual a maximum scope of responsibility and the greatest opportunity for exercising initiative. His ideas on organization have been the source of a number of articles relating to transportation matters.

Mr. Begien believed that a good railroad officer should know the problems of other departments as well as of his own. Accordingly, he would call departmental staff meetings to bring about better understanding of related problems, to foster unified and cooperative action, and so to improve the results of operation. He considered loyalty a most important attribute, and once was heard to say that he would rather have one man who understood his plans and was 100% loyal than a dozen genii.

In his relations with his fellow officers and employees, Mr. Begien encouraged their progress and development as future railway men, and he had the faculty of imparting to them his enthusiasm and knowledge. Several of these men have become heads of important transportation systems; so, if it is true, as has been said, that the Baltimore and Ohio is the mother of railroad presidents, then certainly Mr. Begien's influence on his friends and associates made him the big brother of railroad presidents.

Mr. Begien belonged to a number of clubs, including the Commonwealth Club, the Country Club of Virginia (Richmond), and the University Club (Cincinnati). He was an Episcopalian, and in things political adhered to the Republican Party.

He was a devoted husband, and as a father took a keen interest in the education and welfare of his children. After he retired he lived on Douglasdale Road in Richmond.

A member of the American Railway Engineering and Maintenance of Way Association (later American Railway Engineering Association) in 1907 (life member in 1940), he served on Committee 16—Economics of Railway Location (1908–1923, inclusive) as vice-chairman from 1911–1913 and as chairman in 1914 and in 1919–1920. He also was on the Committee on Wood Preservation (1909–1910) and the Special Committee on Cooperative Relations with Universities (1924–1927). While a member of Committee 16, he directed many dynamometer tests on Baltimore and Ohio freight trains, the results of which were basic freight train tonnage rating formulas.[3] Mr. Begien was the author of a number of papers concerning railway engineering and operation, and served from time to time as a member of the board of directors of a number of corporations allied with the transportation industry.

He was interested constructively in the activities of the Society, especially in the field of railway engineering. In 1923–1924, he was a Director from Zone III.

Mr. Begien was elected an Associate Member of the American Society of Civil Engineers on June 7, 1905, and a Member on March 13, 1917. He became a Life Member in 1940.

WILLIAM ETHELBERT BELKNAP, M. Am. Soc. C. E.[1]

DIED OCTOBER 1, 1942

William Ethelbert Belknap was born in Yonkers, N. Y., on July 20, 1867, one of a large and very distinguished family. His father was Ethelbert Belknap, a highly esteemed and successful hat manufacturer in Yonkers, and his mother was Lydia Elizabeth (Frazee) Belknap. His ancestor, Abraham Belknap of Warwickshire, England, settled in Lynn, Mass., in 1637. Another ancestor, Joseph Belknap, was the founder of the Old South Church, Boston, Mass. In the same line, Samuel Belknap fought in the French and Indian War. John Frazee (1790–1852), Mr. Belknap's grandfather on his mother's side, was an outstanding American architect. He designed the U. S. Sub-Treasury Building on Wall Street, New York, N. Y. (1834–1841). As a great sculptor, Mr. Frazee was a connecting link between American plastic art and the modern period. In 1824–1825, Mr. Frazee made the first marble bust in America—that of John Wells, a New York City attorney. He also did seven busts for the Boston Athenaeum.

William Ethelbert Belknap was prepared for the Yonkers High School in the Rev. Montgomery R. Hooper's Academy for Boys, and was graduated from New York University in New York in 1888 with the degrees of Bachelor of Science and Civil Engineer. Naturally, with his ability and genial disposition, he was elected to Phi Beta Kappa and Psi Upsilon fraternities.

During the summer of 1888 he acted as chainman for the New York State Adirondack Survey.

From February, 1889, to November, 1892, he was with the Pennsylvania Railroad Company in Jersey City, N. J., first as rodman for the engineer of maintenance of way with duties of general assistant on grades, lines, inspection, and surveys. He was promoted to field assistant in responsible charge of location and construction of track and grading for a large roundhouse, storehouses, and boilerhouses. During this same period, he worked on a water supply system in connection with the establishment of the Waldo Avenue Yard in Jersey City, and made miscellaneous surveys for the location of rights of way, sidings, etc.

---

[3] "Basic Freight Train Tonnage Rating Formulas," Committee 16, *Proceedings*, A.R.E.A., Vol. 12, Pt. 1 (1911), p. 330.

[1] Memoir prepared by T. Kennard Thomson, M. Am. Soc. C. E.

He was assistant engineer in responsible charge of construction of the Bay Street Ferry Station in Jersey City and of construction of undergrade crossings for the Port Reading Railroad Company (heavy masonry bridge abutments, elevation of tracks, trestle work, etc.). Mr. Belknap then was engaged on the design and construction of the Jersey City powerhouse of the Consolidated Traction (Railway) Company, dealing especially with trestles, sidings, coal pockets, etc. In addition, he was employed on the plans and construction of the Jersey City electric light and powerhouse for the Pennsylvania Railroad Company, miscellaneous reports, estimates, surveys, etc.

Continuing his service with the Pennsylvania Railroad Company, in October, 1892, Mr. Belknap was transferred to the office of the engineer of maintenance of way, at Altoona, Pa., as assistant engineer in responsible charge of construction of the Altoona and Logan Valley Electric Railway (20 miles of city and suburban track, powerhouse, etc.). This was followed by the construction of Lakemont Park, near Altoona (earth dam, park buildings, etc.), for branch lines, changes of line, etc.

From May to September, 1894, Mr. Belknap was associated with S. L. Cooper,[2] M. Am. Soc. C. E., in making plans for the sewer system at Hastings-on-Hudson, N. Y. He acted as assistant engineer in charge of construction of the extension of Warburton Avenue, near Yonkers; and as consulting engineer for the Lancaster Sea Beach Improvement Company in Far Rockaway, N. Y., on plans for ocean shore protection, roads, and other improvements. Also, Mr. Belknap was consulting engineer for the Brooklyn (N. Y.) Sanitary Company, designing the foundations and planning the wharf work for the garbage utilization plant at Barren Island, New York.

From February, 1895, to January, 1897, he was engineer for the Wallabout Improvement, Department of City Works, Brooklyn, in charge of the design and construction of a large shipping basin (bulkhead, walls, piers, and other wharfage facilities).

From January, 1897, to December, 1902, Mr. Belknap was assistant engineer, Department of Docks and Ferries, New York City, in charge of waterfront operation in the Borough of Brooklyn, dredging, construction of various piers, pier sheds, yacht landing basin, bulkhead walls, crib bulkheads, pile tests, etc.

Mr. Belknap was engaged in the coal business from December, 1902, until 1914—as superintendent on a coaling pier in Jersey City for the Communipaw Coal Company, and as secretary and treasurer of this company; and as secretary and treasurer of Burns Brothers (coal company) whose work was centered in New York and New Jersey. In addition, he had charge of the design and reconstruction of coaling piers, coal pockets, etc.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXVI (December, 1913), p. 2212.

As Mr. Belknap happened to be in England in 1914 when World War I started, he assisted in the evacuation of Americans then in England. He returned to America during the summer of 1914, and, near the end of that year, took his family to Hollywood, Calif.

Early in 1916 he bought the Orchard Gables estate in Hollywood, and that fall moved his family there permanently. He worked for the Red Cross in Washington, D. C., in 1917–1918.

He lived in California until he died, practicing architecture and engineering. Among other buildings, he designed his daughter's house. He was also a water color artist. His favorite sports were boating, fishing, tennis, and golf. He was a good Episcopalian, and a Republican until 1932 when he voted Democratic.

He was married to Helen Brett Runyon on April 22, 1897, who survives him. They were blessed with three children, Carman Runyon, who died in 1937; Ethelbert, who died in infancy; and Isabelle Fitz Randolf (Mrs. Paul Kunasz). He is also survived by three sisters, Ada Blanche Belknap, Edith Beatrice Belknap, Athenia Agnes (Mrs. Thomas Wood Hastings); one brother, Christopher Irving Belknap; and three grandchildren, Paul Belknap Kunasz, Peter Brett Kunasz, and William Runyon Belknap.

William Ethelbert Belknap lived up to the great standard of his outstanding family as a man, engineer, business man, artist, and sportsman. He was always genial, reliable, and true to his family, friends, and associates, whose admiration and affection he constantly held. It was a privilege to have known him. Whatever Mr. Belknap did was modestly and unassumingly well done.

Among his writings are many discussions published in the Society's *Transactions*. He served the Society well, especially when he was a Director for three years from 1910 to 1912.

Mr. Belknap was elected a Junior of the American Society of Civil Engineers on March 31, 1891; an Associate Member on March 6, 1895; and a Member on December 1, 1897.

EDWARD FRANKLIN BERRY, M. Am. Soc. C. E.[1]

DIED AUGUST 28, 1944

Edward Franklin Berry was born on October 1, 1889, in Fredericton, New Brunswick, Canada, the son of Edward Albert and Margaret Jane (Todd) Berry. He received his early education in the public schools of Fredericton, and later attended the University of New Brunswick at Fredericton from which he was graduated in May, 1913, with the degree of Bachelor of Science in Civil Engineering.

---

[1] Memoir prepared by Louis Mitchell, M. Am. Soc. C. E., and J. O. F. Eichler, Assoc. M. Am. Soc. C. E.

While an undergraduate, Mr. Berry held several minor positions during the summer months on surveying parties, and in 1912 was assistant resident engineer on the construction of the St. John and Quebec Central Railroad, in charge of a field party.

After graduation, he became instrumentman for the Quebec Central Railway Company on preliminary and location surveys. From 1914 to 1916, Mr. Berry was chief draftsman on the federal valuation of the Maine Central Railroad Company.

In September, 1916, Mr. Berry was appointed instructor of civil engineering at Lehigh University in Bethlehem, Pa., where he served for three years. During this time he acted as consultant on several structural engineering projects. From 1919 to 1920, he was employed by the Texas Company as editor of its technical periodical, *Lubrication.* He also wrote two textbooks dealing with the subject of lubrication, for schools conducted by the Texas Company.

In September, 1920, Mr. Berry was appointed to the civil engineering staff of the Lyman Cornelius Smith College of Applied Science, Syracuse University, in Syracuse, N. Y., where he served as assistant professor, associate professor, and from 1939 until the time of his death as professor of civil engineering and head of the department of civil engineering, specializing in structural engineering. From 1923 to 1939, he had charge of the Materials Testing Laboratory which was rebuilt under his direction. On numerous occasions he was engaged as consulting engineer.

In addition to the Society, Professor Berry belonged to the following technical and professional organizations: Society for the Promotion of Engineering Education, American Association of University Professors, the American Society for Testing Materials, and the Technology Club of Syracuse. He was one of the founders and the first president of the Upper New York State Section of the Society for the Promotion of Engineering Education. He was also president of the Syracuse Section of the American Society of Civil Engineers in 1935, and a member of the Board of Directors of the Technology Club of Syracuse. In addition to his professional affiliations, Professor Berry belonged to Sigma Xi, Phi Kappa Phi, Theta Tau, and Tau Beta Pi fraternities. He was a Thirty-Second Degree Mason and a member of the University Methodist Church of Syracuse.

Professor Berry was married to Norma J. Vader of Syracuse in 1936. He is survived by his widow and a daughter, Winona N. (Mrs. James Dee).

As a citizen, as an engineer, and as a teacher, Professor Berry had the highest ideals, character, and integrity.

Professor Berry was elected a Member of the American Society of Civil Engineers on November 11, 1929.

PAUL ALEXANDER BLACKWELL, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 9, 1943

Paul Alexander Blackwell was born in Ghent, Carroll County, Ky., on February 13, 1879, the son of James Shannon Blackwell, noted linguist, and Mary Evelyn (Smith) Blackwell.

He attended the University of Missouri at Columbia and received the degree of Bachelor of Science in Civil Engineering in June, 1900. He was a member of Phi Gamma Delta fraternity. Several years after graduation his education was supplemented by study of statically indeterminate structures under J. W. Turm, a graduate student of Prof. J. Melan, of Prague.

In 1900 he was commissioned a Second Lieutenant, Battalion of Cadets, National Guard of Missouri. In 1917 he enlisted as a private in the Virginia Volunteer Infantry, serving, successively, as First Sergeant, Second Lieutenant, First Lieutenant, and Captain.

His engineering career began in 1900 as a structural draftsman with the Koken Iron Works, of St. Louis, Mo. Following this engagement, he served the Fort Pitt Bridge Works, in Pittsburgh, Pa., first as a structural draftsman from 1901 to 1903 and then as designer and estimator from 1903 to 1906. From August, 1906, to April, 1907, he worked for the Riverside Bridge Company, Martins Ferry, Ohio, as designer, estimator, and contracting agent.

In April, 1907, Mr. Blackwell was employed by the Virginia Bridge and Iron Company of Roanoke, Va., as an estimator and designer. A month and a half later, he was made assistant chief engineer. In 1922 he was promoted to chief engineer. He continued in this position until 1936 when the Virginia Bridge and Iron Company became a subsidiary of the U. S. Steel Corporation. The company's name was then changed to Virginia Bridge Company and Mr. Blackwell remained as chief engineer until his retirement on January 31, 1940.

During the years when Mr. Blackwell was assistant chief engineer and chief engineer for the Virginia Bridge and Iron Company, the company experienced its greatest expansion, both as to extent of territory and capacity of plants As chief engineer, he was in charge of designs, estimates, and details of all classes of steel structures furnished by his company. The many and varied types of bridges, buildings, etc., which were designed under his supervision and which are giving excellent service today, testify to his ability as an engineer.

Mr. Blackwell was endowed with an active and receptive mind. Quick to grasp an engineering problem, he always made decisions promptly. He was very systematic in his personal affairs and instilled this attribute into his organization.

In addition to his engineering ability, Mr. Blackwell was a student of several languages. An inquiring mind led him to study and investigate many subjects unrelated to his chosen profession. His quick wit and ready repartee, together with an exceptional fund of information, made him an interesting conversationalist and a person who will not be quickly forgotten by his friends and associates.

---

[1] Memoir prepared by C. W. Ogden, M. Am. Soc. C. E., and George P. Jones and C. R. Wentworth, Assoc. Members, Am. Soc. C. E.

He was married on November 19, 1902, to Emily Frances Little, who survives him.

Mr. Blackwell was elected a Junior of the American Society of Civil Engineers on December 4, 1900; an Associate Member on January 3, 1906; and a Member on January 20, 1920. He became a Life Member in January, 1941.

CLARENCE MOORE BLAIR, M. Am. Soc. C. E.[1]

Died May 21, 1944

Clarence Moore Blair, the son of William Henry and Mary (Moore) Blair, was born on August 21, 1885, in New Haven, Conn., in which city he lived throughout his entire life.

Following his early education in the public schools of New Haven, including Hillhouse High, he entered the Sheffield Scientific School of Yale University, specializing in civil engineering. Receiving honorable mention for excellence in mathematics in his freshman year, honors for excellence in all studies in his junior year (Sheffield at that time had no sophomore year) and general two-year honors in his senior year, he was graduated in 1904 with the degree then given graduates in science: Bachelor of Philosophy.

He at once entered the office of the late Albert B. Hill, M. Am. Soc. C. E., one of the outstanding consulting engineers of Connecticut, and, starting as rodman, by 1913 he had become first assistant in charge of all work. Mr. Hill died in 1930, and Mr. Blair and the late Orson H. Marchant, M. Am. Soc. C. E.—a classmate of Mr. Blair's who also had entered the Hill office on graduation—took over the practice under the name of Blair and Marchant, Inc., Mr Blair being president and treasurer. On the death of Mr. Marchant in 1938, the business was continued as Clarence M. Blair, Inc., Mr. Blair remaining as president and treasurer, and taking in his former assistants in the company as partners.

From its foundation by Mr. Hill the office had been noted for the thoroughness and accuracy of its work. Mr. Hill, a gentleman of the old school, inculcated in his men the same high standard of living and work by which he himself was guided, and Mr. Blair maintained Mr. Hill's principles in full. The reputation of the office brought to it much important work, giving the younger men unusual experience and opportunity. On his first assignment, while nominally rodman on the construction of an interurban electric railway from Cheshire to Waterbury, Conn., across heavy country, Mr. Blair showed such ability that he was put in charge, successively, of the sewage disposal plant for the Taft School at Watertown, Conn.; sewers for Litchfield, Conn.; the Wepawaug tunnel, Watrous dam, and the Gaillard dam and tunnels for the New Haven Water Company; and a number of smaller water and sewerage projects.

---

[1] Memoir prepared by Clarence Blakeslee and Charles Rufus Harte, Members, Am. Soc. C. E.

Upon the death of Mr. Hill, Mr. Blair's work became more of an executive character, but until his final illness he kept actively and closely in touch with the construction as well as the designing and general engineering for a number of Connecticut utilities, towns, and the state itself; and personally represented many of these clients in valuation, rate, and other court cases, the thoroughness of his preparation and his poise making him a particularly valuable witness.

A firm believer in the advantages of organized association, Mr. Blair became a member of Sigma Xi and of The Yale Engineering Association before his graduation. Immediately thereafter, in August, 1904, he was elected a member of The Connecticut Society of Civil Engineers, Inc., and, serving efficiently on many of its committees, he also had the honor, shared by no other member of that society, of having held, successively, every one of the offices from director to president. As secretary-treasurer in the years from 1923 to 1931, he brought the affairs of the society from the very serious condition, in which they were turned over to him, to a high degree of prosperity. In 1941 he was elected an honorary member.

Always interested in the Society, in 1940 Mr. Blair was elected Director for District No. 2, and he served on several important committees. He was active in organizing the Connecticut Section of the Society, of which he was a charter member, and he served as its secretary-treasurer from 1921 to 1931, inclusive. He joined the New England Water Works Association on January 13, 1915, and the American Water Works Association in January, 1938.

In 1930, to fill the vacancy caused by Mr. Hill's death, the Hon. John H. Trumbull, Governor of Connecticut, appointed Mr. Blair a member of the Connecticut Board of Civil Engineers, which at that time had supervision over dams and reservoirs throughout the state. He served on that board and its successor, the State Board for the Supervision of Dams, Dikes, Reservoirs and Other Similar Structures, until his death. He was very active in securing the passage of the state act for the registration of engineers, and, in recognition of his efforts, when he became a "Registered Professional Engineer and Land Surveyor," he was given the first certificate, No. 6, issued to any other than members of the board—the act assigning Nos. 1 to 5, inclusive, to the board. In 1925 he was appointed a member of the Board of Control of the Safety Council of New Haven.

Of a deeply religious nature, Mr. Blair became a member of the Dwight Place Congregational Church when but eleven years old. In 1910 he was elected a member of the financial board of the church, becoming a trustee when the church was incorporated in 1920, and continuing to serve in that capacity until 1924 when he was made a deacon. He held this latter office until his death. From 1914 to 1918 he was associate superintendent of the Sunday school, and was superintendent from 1918 to 1919.

Carrying his belief in the wisdom of organized association into his nonprofessional life, Mr. Blair was a member and a past-president of the New Haven Rotary Club, of which he had also been a director; and he was a member of the New Haven Chamber of Commerce, of which he was a director from 1937 to 1939, inclusive. University conscious, he was chairman of the "'04 S" (Class of 1904, Sheffield Scientific School) Reunion Committee for both 1934 and 1939, and he was vice-president of his class. On the social side he was a member of the Graduates' Club of New Haven, and of the New Haven Country Club.

To the problems laid before him Mr. Blair brought a well-trained, analytical mind; his decisions and reports, made only after thoughtful and thorough study of all sides of the question, could be depended upon absolutely, and any construction entrusted to him was supervised with the same meticulous care. Unlike some other men of marked professional ability, not only was he widely recognized as an outstanding engineer, but he also held the high personal regard of all who were privileged to know and to work with him.

Returning from a brief trip into New Hampshire, on September 8, 1942, at Northfield, Mass., as he was about to enter his car, Mr. Blair slipped and fell, fracturing his hip. The break did not heal properly; several operations were performed; and following the fifth one he died on May 21, 1944. His death removed a fine Christian gentleman, a valuable citizen, and a most capable engineer, of whose life no better epitaph can be written than the two words: "Well done!"

On April 15, 1909, at New Haven, Mr. Blair was married to Fanny Belle Rand, the daughter of Stillman Nehemiah and Belle (Morrison) Rand, who survives him.

Mr Blair became an Associate Member of the American Society of Civil Engineers on December 5, 1911, and a Member on May 15, 1917.

ERIC EDWIN BLOMGREN, M. Am. Soc. C. E.[1]

DIED OCTOBER 11, 1944

Eric Edwin Blomgren, the son of John E. and Maria (Erickson) Blomgren, was born on August 21, 1889, in Norway, Mich. He received his early education in Norway and was graduated from the University of Michigan at Ann Arbor in June, 1916, with the degree of Bachelor of Civil Engineering. For two years, he studied at the graduate school of the University of Michigan, from which he received the degree of Master of Science in Civil Engineering in June, 1918.

Immediately after graduation, Mr. Blomgren became maintenance engineer for the Washtenaw County Good Roads District at Ann Arbor, and in January, 1919, he was appointed assistant engineer for the Wayne County

---

[1] Memoir prepared by H. C. Coons, M. Am. Soc. C. E.

Road Commission in Detroit, Mich. In 1920 because of the illness of his father, a road contractor with headquarters in Norway, he resigned this position.

After his father's death, he was planning engineer for the Ford Motor Company in the "Upper Peninsula" district of Michigan from 1923 to 1926. In 1926 he became plant engineer for the Nash Motor Company in Milwaukee, Wis., and in 1930 he was employed as resident engineer for the Illinois Division of Highways on the Outer Drive in Chicago, Ill.

On July 1, 1933, Mr. Blomgren was appointed maintenance engineer for the Michigan State Highway Department and continued in that capacity until October, 1938, when he became district engineer of the southwest district of Michigan, comprising ten counties. He continued in this position until his death.

Mr. Blomgren was a man of high ideals and unquestionable integrity. His professional ethics were especially high, with the result that he was admired and respected by those with whom he came in contact.

Charles M. Ziegler, then state highway commissioner of Michigan, considered Mr. Blomgren one of his best engineers and an excellent representative in the field who had done outstanding work for the department as district engineer in the Kalamazoo (Mich.) office.

Mr. Blomgren was an active member of the First Presbyterian Church and the Lions Club of Kalamazoo. He was a past-president of the Kalamazoo Engineering Society and a director at the time of his death. He also belonged to the Michigan Engineering Society.

On June 23, 1917, he was married to Ruth Nord of Iron Mountain, Mich. He is survived by his widow; one daughter, Ruth (Mrs. Richard Publow); and two grandsons, Richard Henry Publow, Jr., and Peter Eric Publow.

Mr. Blomgren was elected a Member of the American Society of Civil Engineers on March 10, 1941.

SHERMAN WORCESTER BOWEN, M. Am. Soc. C. E.[1]

DIED AUGUST 19, 1944

Sherman Worcester Bowen, the son of Sherman Worcester and Julia Antoinette (Howard) Bowen, was born in Kimmswick, Jefferson County, Mo., on July 24, 1877. He received his elementary education at Bowen School in Jefferson County, which was named in memory of his father. He was graduated from the St. Louis (Mo.) Manual Training School in 1895 and from Washington University at St. Louis in 1901, with the degree of Bachelor of Science in Civil Engineering. He received the degree of Civil Engineer from Washington University in 1932.

During summers, while attending Washington University, Mr. Bowen worked as draftsman and inspector for the Koken Iron Works in St. Louis and for Brennecke and Fay, consulting engineers. He served with the latter firm from 1901 to 1914 as draftsman, designer, and engineer. During this period he was resident engineer on the St. Louis Municipal Bridge across the Mississippi River. He designed and supervised construction of four reinforced concrete viaducts in Fort Worth, Tex., investigated and reported on river terminals for the City of St. Louis, designed and reconstructed Compton Hill Reservoir in St. Louis, and designed the Robert Roy Bridge for the Cotton Belt Railroad Company. He also constructed various buildings and bridges as a contractor's engineer.

---

[1] Memoir prepared by A. P. Greensfelder, M. Am. Soc. C. E.

From 1914 to 1916 he was office engineer and field engineer for the Department of Public Utilities of the City of St. Louis, supervising construction of an intake tower for the Water Department in the Mississippi River and studying a municipal dock at St. Louis. From 1916 to 1927 Mr. Bowen was engineer on construction for Fruin-Colnon Contracting Company, general constructors of St. Louis, on numerous industrial and commercial structures in the St. Louis metropolitan area. He specialized in foundations and structural work. In 1927 he was elected vice-president of Fruin-Colnon Contracting Company, which position he held until retirement a few weeks before his death.

On October 16, 1901, he was married to Edith Louise Holbert of Bloomington, Ill. He is survived by his widow and four children, Laura Antoinette (Mrs. Charles W. Crews); Sherman Worcester Bowen, III; Charles Holbert Bowen, Lieutenant (j.g.), U. S. Navy; and Howard Basford Bowen, Technical Sergeant, U. S. Army.

Mr. Bowen was a trustee of The First Unitarian Church of St. Louis, a Third Degree Mason of Rose Hill Lodge in St. Louis, and a member of the St. Louis Academy of Science, St. Louis Engineers' Club, and Royal Society of Arts, London (fellow). He was the author of various articles in the technical press—in the Society's *Transactions,*[2] *Engineering News,*[3] *Engineering Record,*[4] and *Civil Engineering*[5]—on work with which he was connected.

Mr. Bowen was elected an Associate Member of the American Society of Civil Engineers on September 7, 1904, and a Member on July 9, 1912.

SAM WIGFALL BRADSHAW, M. Am. Soc. C. E.[1]

Died January 20, 1945

Sam Wigfall Bradshaw was born on April 13, 1874, in Steelton, Pa. His parents, James Gibson Bradshaw and Sarah (Wigfall) Bradshaw, came from England.

After being educated in the Steelton public schools, he left high school one year before graduation to take a position as draftsman with the Bridge and Construction Department of the Pennsylvania Steel Company. From April, 1896, to July, 1897, he was employed by Milliken Brothers in Staten Island, N. Y., as a checker on structural steel drawings. He then returned to the Pennsylvania Steel Company as a drafting room squad leader, advancing to assistant engineer in the Estimating and Designing Department. In 1916 the Pennsylvania Steel Company was purchased by the Bethlehem Steel Company, and Mr. Bradshaw moved to Bethlehem, Pa. He was employed by the Bethlehem Steel Company as assistant engineer.

His was a strong character; and, despite the early termination of his formal schooling, Mr. Bradshaw was, for many years, a devoted student of engineering, particularly in the field of structures. He was closely associated with the designing and detailing of many important bridges, especially with the mechanical features of movable bridges and turntables. His accumulated notes and sketches on these topics were particularly valuable.

A Mason of long standing, he was a life member of the Blue Lodge, a member of the Knights Templar and the Mystic Shrine, and a Thirty-Second Degree Mason of the Scottish Rite. For years he took a very active part in freemasonry, especially in the dramatic consistorial degrees. He also was well versed in Masonic history.

Mr. Bradshaw was a man of broad and distinctly esthetic interests, a lover of flowers, a student of astronomy, and a violinist of real ability. In his younger days he was, for a number of years, an organist in the Protestant Episcopal Church, and participated in community musical ensembles. He was a vestryman of the church, and was versed in church history to an unusual degree for a layman. He was beloved and respected by his many associates in industry and in his community.

On June 22, 1899, in York, Pa., he was married to Etta A. Smith, of Steelton, who survives him.

Mr. Bradshaw was elected a Junior of the American Society of Civil Engineers on October 2, 1900; an Associate Member on February 4, 1903; and a Member on July 6, 1920. He became a Life Member in January, 1938.

---

[1] Memoir prepared by Charles H. Mercer, M. Am. Soc. C. E.

BENJAMIN EDWARD BRIGGS, M. Am. Soc. C. E.[1]

Died October 1, 1944

Benjamin Edward Briggs was born at Sullivan, Ind., on July 26, 1860, the son of Murray and Margaret (Briggs) Briggs.

He received his education in the Indiana Public Schools and studied engineering with the International Correspondence Schools. His first engineering work was on a survey of the Wabash River bottom lands in Sullivan County, Indiana, in 1883. Mr. Briggs served as county surveyor for Sullivan County, and later as engineer for the Indiana and Illinois Southern Railway. His next engagement was with the Coronado Beach Company of San Diego, Calif.

In 1890 Mr. Briggs came to Erie, Pa., and served in the employ of the Pennsylvania Railroad Company. On November 1, 1893, he was appointed assistant city engineer of Erie, and three years later he was promoted to the position of city engineer. He served in that capacity until 1916, and he is credited with many municipal improvements, including the Buffalo Road Viaduct. After 1916 Mr. Briggs was engaged in private consulting practice and was active until a short time before his death.

Mr. Briggs was a highly respected and faithful public servant, who enjoyed the high regard and esteem of all who knew him. He maintained throughout his life the highest standards of conduct, understanding, tolerance, fellowship, human relations, and professional integrity, which have accrued, in his passing, as a legacy of credit to his profession.

On September 19, 1883, Mr. Briggs was married to Cora Saxton. Mrs. Briggs died on June 1, 1937, and in 1939 Mr. Briggs was married to Mrs. Vera Steinrock. He is survived by his widow and a daughter by his first marriage, Margaret (Mrs. Oliver Horton).

Mr. Briggs belonged to the American Society of Municipal Improvements, a national organization of city engineers, and was president in 1912. A founder of the Engineering Society of Northwestern Pennsylvania in 1898, he served as president for two years. He was a member of the Erie Chapter of the Pennsylvania Society of Professional Engineers and also of the Rotary Club of Erie.

Mr. Briggs was elected a Member of the American Society of Civil Engineers on November 4, 1908. He became a Life Member in January, 1933.

---

[1] Memoir prepared by Clarence Pulling, Asst. City Engr., Erie, Pa.

ORRIN LAWRENCE BRODIE, M. Am. Soc. C E.[1]

DIED OCTOBER 5, 1943

Of high intellectual attainments, Orrin Lawrence Brodie combined those qualities of mind, heart, and hand that endeared him, beyond expression, to all with whom he came in contact.

Orrin Lawrence Brodie was born on July 5, 1879, in Pittsburgh, Pa., the son of Henry T. Brodie and Agnes (Bartberger) Brodie. He was educated in the public and high schools of that city. After preliminary surveying work around Pittsburgh, he attended Columbia University in New York, N. Y., from which he was graduated with the degree of Civil Engineer in 1901. He was known to his classmates as "Steve." Following his graduation, he taught surveying and geodesy at Columbia. He then worked for the New York Central and Hudson River Railroad as inspector of retaining walls and bridge abutments; and, later, on the construction of the Pennsylvania Railroad Tunnels under the Hudson River leading into New York. From 1903 to 1906, he was engineer in immediate charge of repaving streets in the Borough of Richmond.

With the New York City Board of Water Supply from 1906 to 1914, Mr. Brodie directed investigations and designs, prepared contract and working drawings and specifications, and conducted special structural and hydraulic studies, all connected with the Catskill Water Supply System.

Mr. Brodie served three years as associate efficiency engineer with the Board of Estimate and Apportionment and Commissioner of Accounts of the City of New York. For one year he was assistant to the Consulting Engineer of the Borough of Manhattan. In World War I, he was engineer for the government nitrate plant at Muscle Shoals, Ala.

From 1919 to 1927, as assistant designing engineer with the Holland Tunnel organization, Mr. Brodie originated highly important methods of tunnel ring stress determination[2] and silt pressure investigations. He returned to the Board of Water Supply in November, 1927, as designing engineer, which position he held at the time of his death. In addition to his routine designing supervision, Mr. Brodie completed the Grant City model studies concerned with the diversion tunnel of the Rondout River at the Merriman Dam, investigations on caisson sinking, and many other studies. He assisted Charles M. Allen, M. Am. Soc. C. E., with the tests at Worcester Polytechnic Institute in Worcester, Mass., for the Rondout stilling pool.

In 1910 Mr. Brodie was the co-author of a well-known technical book, "High Masonry Dam Design."[3] The second edition of this book appeared in 1916 under the title "Masonry Dam Design Including High Masonry Dams." At times, Mr. Brodie was lecturer and instructor in "extramural courses" of the College of the City of New York on "Masonry Construction and Design" and was, also, an instructor at New York University. At other times, he designed dams and reservoirs for private consultants.

---

[1] Memoir prepared by Thomas K. A. Hendrick, Assoc. M. Am. Soc. C. E.

[2] *Transactions*, Am. Soc. C. E., Vol. 109 (1944), p. 737.

[3] "High Masonry Dam Design," by Charles E. Morrison and Orrin L. Brodie, John Wiley & Sons, Inc., 1st Ed., New York, N. Y., 1910.

In the military sphere, Mr. Brodie was a captain, commanding the Third Company, Ninth C. A. C., New York Guard, until placed on the officers retired list. His company of the State Guard protected the Catskill Aqueduct during World War I.

Among Mr. Brodie's hobbies were: An unusually complete workshop in his home, archery, automobiles, and people—his interest in people knew no bounds. Each associate was to him a living entity with aspirations for mutual cooperation. He served as assistant minister at the Protestant Episcopal Church of the Ascension, Staten Island, New York. Also, Mr. Brodie was Past Master of the Richmond Lodge of Free and Accepted Masons. Many people from near and far sought his advice and counsel. He lived the maxim of never causing pain to any one. A guiding quotation, he often mentioned, was: "Before a conscience can be quickened or a will inspired, the mind must know." He placed a high value on his membership in the Society. He also belonged to the Association of Engineers of New York, Inc., and The Society of American Military Engineers; and he was an original subscriber and charter member of the New York Society of Military and Naval Officers, World War I. He was a pre-eminent exemplar of technical and professional efficiency in the civil service, as attested by the following editorial published on October 8, 1943, in the *Staten Island Advance:*

EMINENT PUBLIC SERVANT

"Mr. Orrin L. Brodie, who died recently at his home in Westerleigh, was an outstanding illustration of the civil service employe who performs a role of profound public importance behind the cloak of comparative obscurity which hides the operations of the entire civil service force.

"His name might never have become widely known even on the Island beyond the confines of his own field of professional activity if a story in this newspaper several years ago had not described a series of tests which he conducted in the Department of Water Supply, Gas and Electricity station at Grant City.

"Mr. Brodie, a designing engineer with the city's Board of Water Supply, built an exact scale model of a multi-million-dollar diversion tunnel and reservoir spillway which his board was planning to construct upstate in connection with the vast municipal water supply expansion program. The model was correct to the fraction of an inch in every particular; it was the prototype of the projected tunnel and spillway in every detail, and was used in experiments to determine how various features of the actual project would function under all manner of conditions. By experimenting with the model, Mr. Brodie and his staff were able to decide the best method of designing the ultimate improvement. Incidentally, they saved the taxpayers a considerable sum of money through what they learned in the tests; they produced the most satisfactory final blueprints that could be devised; and they gained some new scientific data which had not been known before.

"Within his own professional circle, Mr. Brodie was highly respected for his accomplishments. These accomplishments—all of them in the public welfare—were many and diverse.

"He assisted in planning the Ashokan dam in upper New York State and the Muscle Shoals dam in Alabama, where he was stationed during World War I. He worked with the Port of New York Authority on the Holland Tunnel plans, and between times held key assignments on other major civic works.

"Through the years he did all this without glorification or acclaim.

"He was an eminent public servant, desiring neither glory nor acclaim for his unremitting efforts."

His sparkling brown eyes bespoke a mental activity of a steel trap variety that was equaled only by his genuine interest and enthusiasm in his fellow Americans without regard to race, color, or creed.

In addition to the inspiration which he gave so generously, Mr. Brodie was most interested in and cordial to his friends and associates. He must know, now, in spirit, that he is enshrined in their hearts.

On October 3, 1905, he was married to Eleanor Van Cott of an historic New York City family. He is survived by his widow; four daughters, Janet (Mrs. Charles F. Flint), Agnes (Mrs. Eduard F. Von Wettberg), Margaret (Mrs. James J. Broderick), and Eleanor (Mrs. Charles McKirdy); seven grandchildren, Eleanor Thayer Flint, Janet Crawford Von Wettberg, Eduard F. Von Wettberg III, Lawrence Orrin Broderick, James Michael Broderick, Agnes Brodie McKirdy, and Charles Robert McKirdy; and one sister, Althaea (Mrs. Martin G. Kindlund).

Mr. Brodie was elected an Associate Member of the American Society of Civil Engineers on July 10, 1907, and a Member on September 3, 1913.

ALBERT MARSHALL BROSIUS, M. Am. Soc. C. E.[1]

DIED OCTOBER 9, 1944

Albert Marshall Brosius, the son of Samuel Hartmann Brosius and Laura (Stephens) Brosius, was born at Baltimore, Md., on July 4, 1869. He was a descendant of John Abraham Brosius of Zweibrücken, Germany, who, on September 24, 1742, arrived in Philadelphia, Pa., on the ship *Robert and Alice.*

From 1885 to 1887 he studied mechanical engineering at Purdue University in Lafayette, Ind.

Until 1905 Mr. Brosius was engaged as draftsman and assistant engineer, on surveys and construction for railroads, irrigation projects, cable and electric street railways, sewers, real estate developments, and subways in California, Georgia, Maryland, Washington, D. C., and New York. He was in charge of sewer design and construction for the City of Baltimore from August, 1898, to March, 1900, and in charge of design and construction of sewers and subsurface structures for Jacobs and Davies on the Hudson River tunnels (New York, N. Y.) from April to December, 1905.

---

[1] Memoir prepared by John W. Van Denburg and Alfred M. Wyman, Members, Am. Soc. C. E.

In January, 1906, Mr. Brosius joined the engineering force of the Sewerage Commission of Baltimore as first assistant engineer. At times he served as acting chief engineer. In 1912 he was appointed chief engineer of the Havana Sewerage and Paving Contract in Havana, Cuba. He remained in Havana until 1914.

For two years he practiced privately in Los Angeles, Calif., during which time he conducted some of the early experiments on mechanical aeration of activated sludge. In 1918 he became superintendent of transportation and materials for the Degnon Contracting Company on the construction of the large depot and ordnance warehouse at Charleston, S. C., for the U. S. Quartermaster Department. From 1919 to 1921, he was senior engineer for the United States Shipping Board, Emergency Fleet Corporation, Washington, D. C. In 1921 he resumed sanitary engineering, in which he was deeply interested, and spent several years with Fuller and McClintock in New York City. He then went to Guatemala for the J. G. White Engineering Corporation to aid in the preparation of a comprehensive report on water supply, sewerage and irrigation, hydroelectric development, and electric railways.

In 1928 Mr. Brosius was employed by the Westchester County Sanitary Commission in Westchester County, New York, where he was engaged in the selection of the general layout of the extensive trunk sewer system for the southern part of that county and on various phases of its design. Subsequently, from 1932 to 1939, as designing engineer with the Department of Public Works of New York City, he took part in the development of a comprehensive plan of sewerage collection and treatment—one of the major projects of its kind in the United States. From 1940 until his death he was in private practice as a consulting engineer on civil and sanitary projects in New York City.

Mr. Brosius commanded the respect of his associates by his wide and detailed knowledge of his profession. He will always be remembered by his friends for his unfailing energy and courtesy and his ready cheerfulness under even the most trying circumstances. He was a regular attendant of St. Bartholomew's Episcopal Church in White Plains, N. Y.

On April 28, 1903, he was married to Edith Helen Coakley, who, with a son, Albert Marshall Brosius, Jr., survives him.

Mr. Brosius was elected a Member of the American Society of Civil Engineers on March 1, 1910.

FREDERICK CHARLES CARSTARPHEN, M. Am. Soc. C. E.[1]

Died January 8, 1944

In the death of Mr. Carstarphen the State of Colorado and the City of Denver lost a wise and cooperative leader and counselor; the engineering profession, a valuable member; and society, a respected and loved friend.

---

[1] Memoir prepared by John E. Field and M. C. Hinderlider, Members, Am. Soc. C. E.

Mr. Carstarphen, a native son of Colorado, was born in Denver on April 1, 1881. He attended grade school, and the old East Denver High School at 19th Street and California Street from which he was graduated in 1900. He was graduated from the Colorado School of Mines at Golden in 1905. He received the degree of Doctor of Engineering from the School of Mines in 1932 for his outstanding contributions and achievements in the mining field, and for promoting technical and scientific treatment of engineering problems.

Dr. Carstarphen was of pioneer stock. Among his ancestors was Charles Carroll, of Carrollton, Md., a signer of the Declaration of Independence. His mother, Annie Josephine Carstarphen, was a Carroll and came as a little girl to Central City, Colo. His father, H. W. Carstarphen, was originally from Hannibal, Mo., the home of Mark Twain. His father first went to Leadville, Colo., in 1879, working on numerous mining town newspapers before he moved to Denver, where he has been for many years on the staff of the *Rocky Mountain News,* the oldest newspaper in Colorado.

Throughout Dr. Carstarphen's professional career new and difficult engineering problems interested him, and he contributed widely to their discussion and mathematical solution not only in mining but also in general engineering. A keen analyst of engineering problems, he was the author of many brochures and articles on technical subjects. His ability with higher mathematics was such that fellow engineers sometimes brought him their problems on which he worked for the sheer pleasure of conquering them. He took a leading part in local activities of engineering groups. At the outbreak of World War II, Dr. Carstarphen was appointed local chairman of the Society's National Committee on Civilian Protection in War Time.

As early as 1900 young Carstarphen worked and experimented on aeronautical problems and phenomena, becoming a kite expert—especially on the lifting power and construction of the box kite to obtain high efficiency. Although only nineteen years old, he achieved such a local reputation that he was employed by one of the Denver newspapers to travel around Colorado and show youngsters how to build and fly a kite.

He was an expert in the designing of reinforced concrete. Among the structures constructed by Dr. Carstarphen is the Ideal Building in Denver (1908)—the first reinforced concrete building in the city. He also designed the outlet and spillways of the Kenwood Dam on Cherry Creek (1934), accepted as one of the best designed and safest dams in Colorado. This dam was constructed to protect Denver against floods.

If Dr. Carstarphen had a specialty, it was the design of aerial tramways. From 1913 to 1923 he was chief aerial tramway engineer for the American Steel and Wire Company of Trenton, N. J. He was engineer for the Colorado Portland Cement Company for some years prior to going to Trenton. From 1923 to 1926 he was vice-president and chief engineer of the Manufacturers Selling Company, at Trenton. He was, at times, consulting engineer to the Bureau of Reclamation of the State of Colorado and to the City of Denver.

A life member of the Colorado Section of the Society, he was also president of the Colorado Society of Engineers (member of the board for eight years). In addition to these engineering societies, he belonged to the American Association for the Advancement of Science, and the American Institute of Mining Engineers (life member). Dr. Carstarphen was a Thirty-Second Degree Mason and a Shriner. Active in civic affairs, he was a recognized leader in promoting the development of the resources of Colorado, not only in the mining field, but also in irrigation farming and related industries.

A detailed list of Dr. Carstarphen's work may be found in *Who's Who in Engineering* for 1921.

He was married to Kate Fullerton in Denver, Colo., on June 23, 1908. Mrs. Carstarphen died in April, 1943. Surviving him are his father; an uncle, W. P. Carstarphen; a brother, Carroll W. Carstarphen; and his four children: Catherine (Mrs. Wells), Charles (Lieutenant, U. S. Navy), Florence, and Marion.

Dr. Carstarphen's outstanding characteristic was neither his technical knowledge nor his ability to meet new problems in a practical way, but his teaching ability—his desire to pass along to others his knowledge and his experience. He was essentially a teacher who delighted in his work and in helping others. The young engineer found in him a wise counselor, and one who was able to impart his knowledge in terms within the understanding of younger and less experienced men. He not only taught and helped young men but also was always available to discuss and to analyze the problems of engineers who had grown rusty, or who had not kept up with engineering progress. This was especially true in the case of higher mathematics when the latest developments were pertinent. He was a man who never lost his sense of humor, and never violated the admonition of "Don't take yourself too seriously." In his contacts he met every one with dignity, respect, and consideration, he never criticized the man, nor questioned a man's motives. Although he criticized and discussed projects, theories, and conclusions, personalities never entered the discussion. His criticisms were constructive and analytical.

Dr. Carstarphen lived comfortably and well and was content and appreciative of his opportunities and rewards, with the result that he did not acquire the wealth which he might have if he had devoted more thought to his own financial advantage. He raised and educated four children, a boy and three girls, in the best American traditions—responsibility, self-respect, and duty. His children and the many young men whom he influenced are the greatest and most enduring monuments to a life well spent.

Dr. Carstarphen was elected an Associate Member of the American Society of Civil Engineers on April 6, 1909, and a Member on May 15, 1917.

CHARLES ROBERT FORAN COUTLEE, M. Am. Soc. C. E.[1]

Died January 1, 1944

Charles Robert Foran Coutlee was born at "Oakland Lodge," near Aylmer, Que., Canada, on January 29, 1867, the son of Maj. Louis Maurille Coutlee, sheriff of the District of Ottawa, Ont., Canada, and Jane Maria (Clegg) Coutlee. He was a descendant of Louis Coutlée, or Coutelet, who, as an ex-soldier of France, emigrated to Canada in the sixteenth century. He received his primary education at Aylmer, and, after being graduated from the Ottawa Collegiate Institute, he entered the Royal Military College of Canada, at Kingston, Ont., Canada, receiving a diploma from that institution in 1886.

---

[1] Memoir prepared by K. M. Cameron, Chf. Engr., Dept. of Public Works of Canada, Ottawa, Ont., Canada.

From 1886 to 1889 he worked for the Canadian Pacific Railway Company as rodman and as assistant engineer on the company's "Short Line," through Maine and on the Crow's Nest Pass tunnel near Fernie, B. C., Canada. He entered the engineering service of the Canadian Department of Railways and Canals in 1889, as leveler on the Soulanges Canal, and from 1892 to 1901 was assistant engineer in charge of the construction of the Cascades Division which included four lift locks with weirs, bridges, and heavy rock and earth excavation. During this period he examined and reported on the proposed canalization of the French River in Ontario, Canada.

When the Soulanges Canal was completed, Mr. Coutlee became a consulting engineer in Vancouver, B. C., Canada—on coal mine surveys, irrigation projects, and railway location near Frank, Alta., Canada (the scene of the disastrous slide which practically obliterated that community). He was also an expert adviser on several court actions. In 1904 the Province of Nova Scotia, Canada, embarking on a program of highway improvment and development, engaged Mr. Coutlee as technical adviser. His report formed the basis of the subsequent provincial highway system.

For many years, the project of a ship canal to connect Montreal, Que., Canada, on the St. Lawrence River with the Great Lakes system, via the Ottawa and French rivers, following the historic route of the early voyagers (of whom Samuel de Champlain is the most notable) had been discussed. The Government of Canada decided on a complete investigation of the possibilities of this scheme, and Mr. Coutlee was assigned to the eastern section (some 140 miles long) from Montreal to Ottawa. After the survey of the Ottawa-Des Joachims section, under E. J. Rainboth, was completed and Mr. Rainboth had resigned, that section (140 miles long) was combined with the Montreal-Ottawa section for final planning under Mr. Coutlee's direction. The result of the investigation is contained in the "Georgian Bay Ship Canal Report, 1908." Although the canal project was not completed, the report, data, and plans have been consulted continually with reference to power developments and related matters. The Georgian Bay Survey was conducted by the Department of Public Works, with which department Mr. Coutlee remained until his retirement in 1932. After the completion of the Georgian Bay Ship Canal Survey, Mr. Coutlee continued to work on surveys and compilation of data for the water resources of the Ottawa River watershed. In this connection, he also studied the possible economic utilization of the watershed, and had responsible charge of the construction and operation of the regulating dams built on that river by the Department of Public Works.

Because of his wide experience and sound judgment, he became counselor to the successive heads of the Engineering Service in the Department of Public Works. Mr. Coutlee cultivated a natural aptitude for observation and deduction, as well as the ability to express himself clearly and concisely in both conversation and writing. An outstanding raconteur, his friendship and companionship were greatly valued. His many acts of charity and kindness sprang from deep-seated personal feeling.

In September, 1895, Mr. Coutlee was married to Daisy Pringle, who predeceased him. Later he was married to Beatrice Maude Fleming, who survives him.

He joined the Canadian Society of Civil Engineers as a student member in 1888, the year after the formation of that society, and was the first chairman of its Ottawa Branch. He was a member of the Astronomical Society of Canada and a past-president of the Royal Military College Club.

Mr. Coutlee was elected a Member of the American Society of Civil Engineers on March 1, 1905.

JAMES COWIN, M. Am. Soc. C. E.[1]

DIED DECEMBER 17, 1943

James Cowin was born in Adrian, Minn., on June 13, 1884, the son of James and Rhoda C. (Moberly) Cowin. He attended the School of Mines of the University of Minnesota at Minneapolis, and was graduated with the degree of Mining Engineer in 1907. He continued his studies at Stanford University in Stanford University, Calif., for a short time. In 1916, when he returned to Stanford for special work, he was given the degree of Civil Engineer. He was a member of the Chi Psi fraternity.

In the summer of 1907, Mr. Cowin was in charge of a party on geological survey for coal outcrops in Utah. In the fall of 1908 he went to Mexico and was cyanide foreman for the Real Del Monte y Pachuca Mining Company at Pachuca, Mexico. For a short time he served as engineer for Spurr and Cox, Consulting Engineers of Mexico City, Mexico.

In 1909 Mr. Cowin entered the office of C. A. P. Turner, M. Am. Soc. C. E., reinforced concrete engineer of Minneapolis, as draftsman and designing engineer. In 1910 he opened an office in Winnipeg, Manitoba, Canada, for Mr. Turner, of which he was local manager until 1913. In that year he was transferred to Houston, Tex., as local manager. In 1914 he organized and was president of the company of Cowin and Fee, Ltd. (later Cowin and Company, Ltd.) in Winnipeg. The company specialized in reinforced concrete engineering. In 1915 Mr. Cowin returned to Minneapolis and founded the engineering firm of Cowin and Company, Inc., of Minneapolis.

After the United States entered World War I, he went to St. Louis, Mo., as chief engineer at the St. Louis Clothing Depot for the U. S. Army. In 1918 he returned home and formed the Indian Bolt and Nut Company as an affiliate of Cowin and Company, Inc. This company was later sold. He also incorporated the Steel Service, Inc., of San Francisco, Calif., for warehousing reinforcing steel. He sold his interest in this company in 1929. His engineering companies both in Canada and the United States prepared plans for many notable structures in all of which Mr. Cowin took a personal interest.

---

[1] Memoir prepared by H. B. Henderson, M. Am. Soc. C. E.

Mr. Cowin had vision and an inventive mind. He built up Cowin and Company, Inc., from a small company devoted exclusively to the engineering and fabrication of concrete reinforcement into a successful manufacturing firm with many diverse products. The company's output included unique, modern types of steel storage buildings, corn cribs, and other farm equipment designed in steel by Mr. Cowin.

After the entry of the United States into World War II, Cowin and Company, Inc., turned to the production of steel products for war use. Difficult forgings, a special flexible bending die for shaping steel angle frames for oil tankers, and many other ingenious and difficult operations were developed by Mr. Cowin to aid the war effort. Most of the company's facilities were engaged in war work at the time of his death.

He was an associate editor of "Reinforced Concrete and Masonry Structures,"[2] writing the chapter on "Finishing Concrete Surfaces."

Mr. Cowin was a Christian gentleman, quiet and unassuming. His many kindly acts were done unobtrusively. He was a good friend and intensely loyal. Although he was modest, he was determined and persistent in accomplishing anything he had made up his mind to do.

Mr. Cowin was a member of the Minneapolis Club, the University Club of St. Paul, Minn., the Engineers Club of San Francisco, and Minnesota Engineers Club. He belonged to the American Institute of Mining and Metallurgical Engineers. He was a member of Westminster Presbyterian Church of Minneapolis.

Mr. Cowin was married on February 28, 1912, to Lorilla Martha Rice of Minneapolis, who died in 1928. Two children, Lorilla Mary (Mrs. Elwood Molander) and James, Jr., Lieutenant in the U. S. Army Air Force, survive him. On September 24, 1936, Mr. Cowin was married to Marion Parsons of Fergus Falls, Minn., who also survives him. Other survivors are a sister, Ethelwyn (Mrs. H. Morton); and three brothers, Alton, Percy, and Clifford.

Mr. Cowin was elected an Associate Member of the American Society of Civil Engineers on March 14, 1916, and a Member on June 2, 1920.

LEONARD MARTIN COX, M. Am. Soc. C. E.[1]

DIED DECEMBER 12, 1943

One of the Civil Engineers whose service in the Navy was intimately associated with the early development of the steel floating dry dock died at the age of seventy three, at Saint Helena, Calif. His active professional career as an officer in the Civil Engineer Corps of the Navy covered the period from 1899 to 1923.

---

[2] "Reinforced Concrete and Masonry Structures," G. H. Hool and W. S. Kinne, Editors-in-Chief, 1st Ed., McGraw-Hill Book Co., Inc., New York, N. Y., 1924, p. 132.

[1] Memoir prepared by C. A. Carlson, M. Am. Soc. C. E.

Leonard Martin Cox was born in New Liberty, Ky., on March 21, 1870, the son of Attilla and Kate (Martin) Cox, members of a pioneer Kentucky bluegrass family.

After attending the public schools of Louisville, Ky., and being graduated from the Louisville High School, Mr. Cox entered Rensselaer Polytechnic Institute in Troy, N. Y., from which he was graduated in 1892 with the degree of Civil Engineer. While at college he was elected to membership in the Theta Delta Chi fraternity.

From 1892 to 1895 Mr. Cox was employed as an assistant engineer on railroad work, bridge erection, and maintenance of way by the Louisville, Henderson and St. Louis Railway Company. From 1895 to 1899 he was with a power and manufacturing plant in Louisville; served one year as professor of chemistry at the Louisville Male High School; and, from June, 1898, to January, 1899, was assistant engineer for the Louisville and Nashville Railroad Company on the Nashville (Tenn.) terminals.

His naval career began as the result of an open competition examination, whereby he won a commission as Assistant Civil Engineer, U. S. Navy, with the rank of Lieutenant (j.g.), in January, 1899. He was advanced through the succeeding grades up to that of Captain prior to his retirement in 1923.

His first duty was at the New York (N. Y.) Navy Yard under one of the senior Civil Engineers of the Navy, Peter C. Asserson,[2] M. Am. Soc. C. E., then Captain (C.E.C.), U. S. Navy, and Head of the Yards and Docks Department of the yard. At that time, the reconstruction of Dry Dock No. 2 was the major project.

From 1901 to 1903 Lieutenant Cox served as Head of the Department of Yards and Docks under the Governor of Guam. Probably one of the earliest public works undertaken by the United States in its new capacity in colonial government was the dam and storage reservoir built by the young engineer to furnish a water supply to the native town of Agaña, also the seat of the naval government. His report on the Island of Guam was later published as a public document.

From July, 1903, to February, 1906, Lieutenant Cox served as Supervising Civil Engineer in charge of construction of the floating dry dock *Dewey,* then building at Sparrows Point, Md. This duty, combined with his earlier experience at the New York Navy Yard on the construction of masonry graving docks, led him to a study and investigation of the comparative merits of graving docks versus floating docks for naval purposes. Upon completion, the *Dewey* was towed to Solomons Island, Maryland, where sufficient depth of water permitted complete tests to be conducted, including the docking of the battleships *Colorado* and *Iowa,* and the complete cycle of self-docking operations during the month of July, 1905. The *Dewey,* having completed satisfactory contract requirements, was accepted by the Navy Department.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 96 (1932), p. 1397.

Civil Engineer Cox resigned from the Navy in February, 1906, in order to assist his father, who was ill, by serving as chief engineer of the Louisville, Henderson and St. Louis Railway Company.

At the December, 1906, meeting of the Society, Mr. Cox presented a paper on "The Naval Floating Dock—Its Advantages, Design and Construction."[3] This paper was judged worthy of special commendation for its merit as a contribution to engineering science, and the author was awarded the Norman Medal by the Society in 1907.

In April, 1907, by special act of Congress, Mr. Cox was reinstated in the Navy as a Civil Engineer, with the rank of Lieutenant. In the period between 1907 and 1909, he served at the Norfolk (Va.) and the New York navy yards, and at the latter yard was placed in immediate charge of the construction of Dry Dock No. 4 by direction of the Chief of the Bureau of Yards and Docks.

From 1909 to 1911, Lieutenant Cox was assistant to the Chief of the Bureau of Yards and Docks, Richard C. Hollyday,[4] M. Am. Soc. C. E., then Rear Admiral (C.E.C.), U. S. Navy, serving as Executive Officer, and also in immediate charge of design of maritime works at a time when planning for future dry dock construction was being given much consideration. He was one of the senior Civil Engineers who was called into consultation by the Chief of the Bureau of Yards and Docks on the solution of the foundation problems encountered in the building of the Pearl Harbor (Hawaii) Dry Dock, and is credited with contributing materially to the final plans under which the dry dock was successfully built.[5]

From September, 1911, to January, 1915, Lieutenant-Commander Cox was Public Works Officer at Norfolk Navy Yard, in complete charge of public works, including the extension of Dry Dock No. 3. During this tour of duty, he was appointed by the Hon. William Howard Taft, then President of the United States, as a member of the First Alaska Railroad Commission, of which J. J. Morrow,[6] M. Am. Soc. C. E., then Colonel, Corps of Engineers, U. S. Army, was president. The Commission traveled some 13,000 miles, investigating various railroad sites in Alaska, and submitted a report which was published as a public document and formed the basis for subsequent preparation for that work. In June, 1912, Lieutenant-Commander Cox was appointed Navy delegate to the International Navigation Congress, held at Philadelphia, Pa.

From January, 1915, to October, 1916, he served as Public Works Officer, New York Navy Yard, in general charge of public works construction, including construction of piers and a new layout of yard for battleship construction, as well as of constructing the first modern shore establishment supply buildings.

From October, 1916, to February, 1917, under special orders of the Navy Department, Commander Cox investigated all available sites for naval bases in the West Indies, making examinations of the various available harbors of the islands of Cuba, Haiti, Santo Domingo, and the St. Thomas group; also, he investigated and reported on possible sources for a water supply to the naval base at Guantánamo, Cuba.

---

[3] "The Naval Floating Dock—Its Advantages, Design and Construction," by Leonard M. Cox, *Transactions*, Am. Soc. C. E., Vol. LVIII (June, 1907), p. 97.

[4] For memoir, *ibid.*, Vol. 102 (1937), p. 1564.

[5] "Pearl Harbor Dock," by H. R. Stanford, *ibid.*, Vol. LXXX (December, 1916), p. 223.

[6] For memoir, *ibid.*, Vol. 103 (1938), p. 1846.

From September, 1917, to November, 1918, he was Public Works Officer of what was later the Eleventh Naval District, where he initiated layouts, design, and construction of naval improvements at San Diego and San Pedro, Calif., including the Naval Air Station on North Island; the Marine Expeditionary Base, Training Camp, and preliminary studies for the new Naval Hospital in San Diego. From December, 1918, to June, 1919, he was assistant manager of Division Shipyard Plants, Emergency Fleet Corporation in Philadelphia.

From June, 1919, to May, 1923, Captain Cox served as Public Works Officer at the Mare Island (Calif.) Navy Yard charged with all public works and investigation of naval base sites on San Francisco (Calif.) Bay, as well as the project for the conservation of the Mare Island Navy Yard as a docking and repair base for capital ships.

He was a member of the Engineering Institute of Canada; the Army and Navy Club in Washington, D. C.; and the Engineers Club, the Commercial Club, and the Commonwealth Club of San Francisco.

Captain Cox retired from naval service in May, 1923, due to physical disability. After his retirement, he lived in Vallejo, Calif., where he became interested in civic affairs, and was one of the founders and directors of the Mechanics and Merchants' National Bank. In June, 1927, he became co-publisher with Luther E. Gibson of the *Vallejo Evening Chronicle.* In 1932 he gave up active interest in the newspaper and built a home called "Malvern Woods," just north of Saint Helena to secure some relief from acute attacks of asthma.

Throughout his career, Captain Cox was most keenly interested in plans to augment major shore facilities of the Navy such as dry docks, building ways, quay walls, piers, power plants, and transportation systems, so that the navy yards would be able to meet the needs of the fleet in time of war. His early studies and experience with floating docks brought him into contact with some of the leading civil engineers of England, such as L. E. Clark and Charles Standfield, under whose design the New Orleans (La.) or Algiers (La.) floating dock had previously been built. His paper on floating docks entered fully into the design and construction of such docks, and presented a detailed analysis for the dry dock *Dewey* with respect to loadings, stability, strength, and deflection calculations. This paper received serious consideration from other floating dock designers and led to interesting discussions. The merit of floating docks as compared with graving docks from a naval standpoint, on account of their mobility, was advanced. Civil Engineer Cox agreed with the idea that a floating dock could be used as a part of a repair station that could be taken to locations most accessible to the fleet in time of war. Such a project had previously been suggested by A. C. Cunningham,[7] M. Am. Soc. C. E., then Civil Engineer, U. S. Navy, in an article entitled "The Movable Base."[8] These two officers, having been closely associated in the design and construction of the floating dry docks, were no doubt in a large measure responsible for bringing to the general attention of naval officers, and the service at large, the military value of the floating dock as a naval auxiliary for service with the fleet.

---

[7] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXI (December, 1917), p. 1691.

[8] *U. S. Naval Institute*, March, 1904, p. 181.

Captain Cox, through his duty at various stations and his contact with officers of ability in the line and staff corps, was recognized as being a man who was broadly interested in the Navy as a whole and a man whose professional ability was outstanding. His duties at times necessarily required him to present comments and recommendations not only on strictly professional problems, but on matters most pertinent to the administration of the public works activities, both at naval stations and in the Bureau of Yards and Docks. Even though the question might be highly controversial, his personality and integrity were such that his views were given the fullest and most serious consideration. Undoubtedly, the soundness of his forward looking plans as to measures for the advancement of the Navy in respect to its shore bases has been reflected in developments later applied to the logistic phases of World War II.

Captain Cox was held in high esteem by his superiors and his immediate staff, and inspired in his associates a zeal to carry out the task at hand. He left many friends among the workmen of Mare Island and citizens of Vallejo, and, although his death occurred twenty years after his retirement from the Navy, many were the sincere expressions of sympathy and appreciations of his high character and accomplishments.

On October 16, 1895, Leonard M. Cox was married to Jane Castleman, of Louisville. He is survived by his widow and a daughter, Katherine Castleman Cox.

Captain Cox was elected an Associate Member of the American Society of Civil Engineers on October 4, 1899, and a Member on January 5, 1904.

CLARE HARMON CURRIE, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 17, 1942

Clare Harmon Currie was born in Webster City, Iowa, on May 15, 1882, the son of Frank S. and Sarah (Risdon) Currie. He was educated in the Webster City public schools and was graduated from the local high school in 1900. He entered Iowa State College at Ames and was graduated in 1905 with the degree of Bachelor of Science in Civil Engineering. While in college, he excelled in track and maintained a keen interest in Iowa State College athletics throughout his lifetime.

In 1906 and 1907 Mr. Currie was with the Oregon Short Line Railroad Company on railroad location, where he received his pioneer training in the wild west country of Oregon, Utah, and Wyoming. Immediately after graduation he had worked in Salt Lake City, Utah, for a paving and water works contractor and later for the city.

---

[1] Memoir prepared by Anson Marston, Past-President and Hon. M. Am. Soc. C. E., and Fred H. Austin and J. S. Dodds, Members, Am. Soc. C. E.

The county drainage program was beginning in Iowa about that time, and in the fall of 1907 Mr. Currie left railroading and returned to Hamilton County, Iowa, where he was county drainage engineer for nearly two years. Then, in the summer of 1909, he became city engineer of Webster City in charge of a new paving program. He also continued as consulting engineer on land drainage matters. Between 1911 and 1919 he was a consultant on municipal engineering projects.

In 1919 Mr. Currie organized the Currie Engineering Company, which was active, until his death, in the municipal engineering field in Iowa, Minnesota, Illinois, Arizona, and California. Although Mr. Currie specialized in sanitary engineering and designed many very successful sewage disposal plants, he also was interested in paving, water works, land drainage, and valuation projects in the area served by his firm. He was a pioneer in the beautification of municipal sewage disposal plants.

One of his last important assignments in Iowa was on the Okoboji-Spirit Lake area sewage disposal improvement for the state. Earlier Iowa sewage disposal installations by Mr. Currie are at Boone, Clear Lake, Clarion, Creston, Decorah, Iowa City, Osage, Storm Lake, and Webster City. During this time he was also consulting engineer on water plants at Eagle Grove, Hamburg, and Avoca, Iowa. Mr. Currie applied many newly discovered principles to his sanitary engineering designs. At Mason City, Iowa, Mr. Currie, working with the Iowa Engineering Experiment Station at Ames, developed a very successful double filtration sewage disposal plant for the effluent from the Decker Packing Plant, thus solving a most unsatisfactory stream pollution problem.

The Webster City sewage plant, however, was his pride and joy. The last installation which he had designed and directed personally, he considered it to be of the finest and most modern construction and regarded it as a monument, both to himself and the city.

The Currie firm had an office at San Bernardino, Calif., directed by Mr. Currie's brother, Frank S. Currie, M. Am. Soc. C. E. In California some beautiful sewage disposal plants were designed for various towns, including Colton, El Monte, Huntington Beach, Laguna Beach, Newport Beach, Oxnard, Pasadena, Redlands, San Bernardino, San Clemente, Seal Beach, and Visalia. These sewage plants serving beach cities involved interesting features such as underwater outlets into the ocean, tank skimming by compressed air, and controlled ventilation. Every effort was made to create attractive plants.

An active and valuable member of the Iowa State Board of Engineering Examiners for twelve years, Mr. Currie belonged to the Iowa Engineering Society and was president of the Iowa Section of the Society. He helped to organize the Iowa Sewage Works Conference and was a member of the American Water Works Association.

Mr. Currie had a lovable nature and was devoted to his family and his engineering affiliations. His acquaintances included prominent men in all walks of life and in all parts of the United States. A genial companion, he was ever ready with a good story to illustrate his conversation.

In 1910, at Fairmont, Minn., he was married to Jessie Wohlhuter. Besides his widow, he is survived by two sons, David, Assoc. M. Am. Soc. C. E., First Lieutenant, U. S. Army, and Frank; and by a daughter, Jane (Mrs. William McGahey).

Mr. Currie was elected an Associate Member of the American Society of Civil Engineers on April 1, 1914, and a Member on October 8, 1918.

EDOUARD JEAN BERNARD DE MEY, M. Am. Soc. C. E.[1]

DIED NOVEMBER 20, 1943

Edouard Jean Bernard de Mey was born at Detroit, Mich., on October 25, 1889, the son of Emile J. de Mey and Marie R. (Bagard) de Mey. Until about 1914, his father was American representative of Count Alfred de Monti Bello, and then he became Belgian Consul in Philadelphia, Pa.

Mr. de Mey's early training was obtained in private schools in Boston, Mass., and Philadelphia, and his technical education at the University of Pennsylvania at Philadelphia, from which he was graduated with the degree of Bachelor of Science in Civil Engineering in 1910.

His first engineering experience was with the S. Morgan Smith Company, of York, Pa., where, as construction engineer, he had charge of the erection of pattern and mill buildings. Following this, for two-and-one-half years, he served the Baltimore and Ohio Railroad Company as chainman, leveler, and finally inspector in charge, representing the company on the Ludlow Avenue Viaduct in Cincinnati, Ohio. He next was employed by the City of Cincinnati, as assistant engineer, Division of Structures. During this time he had immediate charge of extensive reinforced concrete viaduct construction.

In 1915 Mr. de Mey became associated with Toupet, Bell and Conley, Inc., Contracting Engineers of Pittsburgh, Pa., as construction engineer in charge of supervision, design, and office work. From 1917 to about 1922, he was chief engineer in general charge of the company's affairs. In 1923, with Mr. Conley, he formed the partnership of Conley and de Mey. This firm specialized in building construction. On the death of Mr. Conley in 1928, Mr. de Mey practiced general engineering until 1932 when he joined the firm of Edward Crump, Jr., Inc., Contracting Engineers of Pittsburgh, as chief engineer and vice-president, remaining until his death.

Mr. de Mey was also interested in technical writing and translated various German and French technical publications into English, among them *Treatise on French Locomotives* by Pechot.

---

[1] Memoir prepared by Eber J. Ellsworth and Bennett Taylor Gordon, Assoc. Members, Am. Soc. C. E.

A life member of the Congress of Navigation, Brussels, Belgium, he also belonged to the University Club and the Pittsburgh Athletic Association. He was a member of Calvary Protestant Episcopal Church. A loyal alumnus, he was very active in the work of the alumni association of the University of Pennsylvania.

Mr. de Mey was elected a Junior of the American Society of Civil Engineers on January 2, 1912; an Associate Member on May 15, 1917; and a Member on January 18, 1921.

HERMAN FRANCOIS DOELEMAN, M. Am. Soc. C. E.[1]

Died May 30, 1944

Herman Francois Doeleman, the son of Adriaan and Wilhelmina (Was) Doeleman, was born on August 25, 1874, in Hooge Zwaluwe, Netherlands, with which locality his family had been identified for several hundred years. He attended the Zierikzee High School and upon graduation went to Amsterdam, Netherlands, and studied engineering at the Royal Institute of Engineers.

In 1893 Mr. Doeleman came to the United States. It was natural that the Chicago (Ill.) World's Fair, which was then opening, attracted him. In Chicago he found employment, but several years passed before he was able to obtain a position in which he could apply his engineering knowledge.

During the period from 1896 to 1904, he was with various iron concerns in Chicago and New York, N. Y. In Chicago Mr. Doeleman was engaged as a draftsman by the Chicago Architectural Iron Works and for a short time by Winslow Brothers. In May, 1900, he went to New York and was employed as a draftsman by Levering and Garrigues and later as a designing engineer in the office of George K. Hooper, consulting engineer. In October, 1900, he was a draftsman for Milliken Brothers, and within the next four years became a checker and finally a squad man.

In March, 1904, Mr. Doeleman started with the American Bridge Company as estimator and designer in the New York office. Four months later he was transferred to Baltimore, Md., as the office engineer and assistant to H. Ashton Ramsay, the contracting manager. After serving for eight years in this capacity, he became chief engineer at the Baltimore plant of the Carnegie Steel Company. During this time Mr. Doeleman made many friends in Baltimore, where he was to reside for the remainder of his life. These friends were his greatest asset in the following years.

In January, 1913, he left the Carnegie Steel Company to go into private practice. He established his office in Baltimore as a consulting engineer, specializing in the design and supervision of the construction of steel and reinforced concrete structures, mainly buildings.

---

[1] Memoir prepared by Howard L. Crandall, M. Am. Soc. C. E.

Shortly after the United States entered World War I, Mr. Doeleman was selected for and accepted a commission as Major under Lincoln Bush,[2] Past-President and Hon. M. Am. Soc. C. E., Colonel in the Construction Division of the United States Army. Mr. Doeleman and some of his former employees were in Washington, D. C. After the war, he was an officer in the Corps of Engineers reserve and received active training at the Reserve Officers' Training Camp. In 1930 he was commissioned a Lieutenant Colonel.

After World War I, in 1919, Major Doeleman reopened his office in Baltimore and remained in private engineering practice until his retirement. In private practice he was the consulting engineer on the construction of a number of industrial plants and buildings, a complete list of which would be too lengthy to include herein. A few of the structures are the Baltimore Trust Building (O'Sullivan Building), Standard Oil Building, the Baltimore War Memorial, a number of buildings in the Johns Hopkins Hospital and University groups, the Western and Eastern schools in Baltimore, and the Gymnasium Building at the United States Military Academy in West Point, N. Y.

In 1940 Millard R. Tydings, U. S. Senator from Maryland, then chairman of the Committee on Appropriations of the U. S. Senate, having considered several reports on the condition of the roof framing over the House and Senate wings of the Capitol, suggested that a report be obtained from still another engineer, this report to be final. Colonel Doeleman was designated to make the necessary survey and render a report. His investigation sustained the previous reports and Congress authorized the reconstruction. Colonel Doeleman was consultant to the Office of the Architect of the Capitol under whose supervision this work was done. His paper on the "Investigations for Roofs of U. S. Capitol"[3] was delivered before the Structural Division of the Society at the 1941 Spring Meeting in Baltimore.

Colonel Doeleman was liked and respected by his associates and subordinates. One of his characteristic traits was helpfulness to his employees. To work under him was an excellent education. He required each man to understand every step of any work, instead of merely following orders.

Although engineering was his lifework, Colonel Doeleman was noted, too, for business and financial judgment and for knowledge of men and events, contemporary and historic. In his writing, in speeches, and in conversation, his erudition and delightful wit were equally apparent. His searching intellect found expression and satisfaction in world travel, omnivorous reading, and in the study of languages—Dutch, English, French, German, Spanish, Italian, and, finally, Russian and Sanskrit—as well as in the more prosaic recreations of bridge playing and gardening.

He was rejected for active military duty in World War II, but gave valuable civilian service as chairman of the Structural Division of the Maryland Section of the Committee on Civilian Protection in War Time and as Protective Construction Specialist of the Third Civilian Defense Region.

During his professional career, Colonel Doeleman was quite active in various technical societies including—besides the Society—the American Concrete

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 107 (1942), p. 1695.

[3] *Civil Engineering*, June, 1941, p. 327.

Institute and the American Institute of Consulting Engineers (elected member of council in 1943 for a three-year term). He was President of the Maryland Section of the Society in 1926. In addition, he was a member of the Engineers Club and the Merchants' Club of Baltimore and trustee of the Baltimore Efficiency and Economy Commission. In his later years he was, also, president of Belt's Wharf Warehouses, Inc.

Colonel Doeleman was married twice. His first wife, the former Emma Blankfard of Baltimore, to whom he was married in 1903, died in 1930. He is survived by his second wife, Natalie Brainerd Doeleman, of Westfield, N. J. (sister of Harold A. Brainerd, Assoc. M. Am. Soc. C. E.), to whom he was married in 1931. There were no children.

Colonel Doeleman was elected an Associate Member of the American Society of Civil Engineers on June 24, 1914, and a Member on September 11, 1917.

THOMAS LINUS KEITH DONNELLY, M. Am. Soc. C. E.[1]

DIED DECEMBER 20, 1943

Thomas Linus Keith Donnelly was born at Bay City, Mich., on May 16, 1882, the son of Thomas Brady and Lillie (Keith) Donnelly. After graduation from Saint James High School at Bay City in 1900, he studied civil engineering at the University of Notre Dame du Lac at Notre Dame, Ind., and was awarded the degree of Civil Engineer.

After spending two years in the field for the Michigan Central Railroad Company and a short period with the Chicago and North Western Railway Company, he went with the Chicago, Rock Island and Pacific Railway Company on construction and location. He was assistant engineer in the Gary (Ind.) city engineer's office, assistant engineer, Constructing Quartermaster's Division, U. S. Army, and then superintendent for the American Asphalt and Rubber Company, before rejoining the staff of the Michigan Central Railroad Company as assistant engineer of terminal construction. He remained with this company from 1909 until 1914.

When the Pere Marquette Railway Company was reorganized in 1914, Mr. Donnelly was employed on the valuation of that railroad for the federal court by Mortimer E. Cooley, Hon. M. Am. Soc. C. E., and Henry E. Riggs, Past-President and Hon. M. Am. Soc. C. E. He continued this work on the valuation of the New Jersey Public Service Electric Railway Company and on the valuation of the Detroit Edison Company. As copartner of the firm of Wenzell, Donnelly and Company, Mr. Donnelly engaged in private practice in Detroit, Mich., and concurrently was assistant professor of civil engineering at the University of Detroit.

Commissioned a Captain in the Engineer Reserve Corps, he entered active duty in World War I as Commander of Company A, Forty-Eighth Engineers, and served as division engineer, First Division Railways, Advance Section, American Expeditionary Forces. Mr. Donnelly for many years participated actively in the Reserve Corps of the Army, attaining the rank of Lieutenant Colonel, Corps of Engineers, Army of the United States. He was a member of the Reserve Officers Association, the Veterans of Foreign Wars of the United States, and the American Legion.

---

[1] Memoir prepared by Eugene I. Van Antwerp, Assoc. M. Am. Soc. C. E.

After the war Colonel Donnelly returned to the firm of Cooley, Riggs and Anderson to work on public utility appraisals. The next six years he spent on docking, dredging, and highway construction, as engineer and as principal engineer. He assisted Professor Riggs on depreciation studies and valuations for many railroads and other utilities. For two years he served as engineer for the Construction Division of the S. S. Kresge Company, for four years as district maintenance engineer for the Michigan State Highway Department, and for two years he practiced privately. Since 1938 Colonel Donnelly had been engaged in private and consulting practice in Bay City.

Professor Riggs has said of Colonel Donnelly:

> "He was a thoroughly competent railway maintenance and construction Engineer. He was a quiet, unassuming, and dependable worker, a good man to work with and be with, and a general favorite in any organization on account of these qualities. I rated him as a high class dependable member of the staff, a competent and experienced engineer and a good citizen. It was with very sincere regret that I read in *Civil Engineering* of his passing."

One of his former associates, Frank M. Bowen, M. Am. Soc. C. E., stated:

> "Tom Donnelly was an engineer of proven ability and possessed a never failing sense of humor. His presence in any organization served as a welcome tonic to everyone. I do not believe he ever caused injury to anyone by word or deed, intentionally. He was an excellent husband and father, a real friend and citizen, and a man whose passing we could ill afford."

In 1907 Colonel Donnelly was married to Magdalen Whetstone, daughter of Mr. and Mrs. Charles Whetstone of Niles, Mich. He is survived by his widow; three children, Thomas Keith, Magdalen, and Polly A.; and five grandchildren, Thomas L. K., Dennis Louis, Brian Kevin, Beirbre, and Michael Donnelly.

Colonel Donnelly was elected a Member of the American Society of Civil Engineers on August 29, 1927.

EDWARD BROWN DONOHUE, M. Am. Soc. C. E.[1]

DIED FEBRUARY 9, 1944

Edward Brown Donohue was born in the Village of Cherokee, Iowa, on March 28, 1896. His parents were Florence and Matilda (Brown) Donohue.

---

[1] Memoir prepared by Fred G. Birch, Assoc. M. Am. Soc. C. E.

His father died when Brown Donohue was eight years old; soon thereafter the family moved to Glendive, Mont., where they made their home until they went to Thermopolis, Wyo. There young Brown took an active part in school affairs and developed into a baseball and basketball player of note; later, while at the University of Notre Dame in Notre Dame, Ind., he became a high jumper of exceptional skill.

His schedule of educational and technical activities, submitted with his application for membership in the Society, is a very modest résumé of more than ordinary attainment. This record reveals his graduation from Thermopolis high school in 1914; his study of civil engineering at the University of Notre Dame from 1915 to 1917; and a year (1917) as chief of party at Thermopolis doing mapping, subdivision, and location of oil placer claims. Then, in 1918, heeding the national call for competent men, he enlisted with the Fourteenth Transportation Corps of the United States Army, becoming a Sergeant First Class and later acting as chief clerk and assistant engineer, Maintenance of Way, Touraine Division, in France.

After the Armistice and until 1921, he was employed, successively, as an engineer by the Wyoming Highway Commission, the City of Helena (Mont.), and the Montana State Highway Commission in many capacities. He then became attached to the highway engineering staff and in the years until 1937 was regularly advanced from one responsibility to another through many departments, being a resident engineer, a division engineer, state maintenance engineer, and finally assistant chief engineer handling a road program worth approximately $15,000,000. As an extra activity, he organized and developed the Montana Highway Patrol to a position of national prominence.

A change in state administration retiring him from the highway staff, Mr. Donohue became chief engineer of the Montana State Water Conservation Board and in November, 1938, assumed the additional duties of state engineer; his responsibility in these two positions entailed the construction of approximately $8,000,000 worth of public projects. It is notable that during his employment by the State Highway Commission he was able to complete his college work and in June, 1924, was graduated from the University of Wisconsin, at Madison, with the degree of Bachelor of Science in Civil Engineering.

In August, 1941, the Hon. Sam C. Ford, Governor of Montana, granted him a leave of absence to act as a project manager responsible for the design of a 35,000-man United States Army cantonment—a $30,000,000 project to be erected at Henrys Lake at West Yellowstone, Mont. The magnitude and difficulties of this undertaking began to reveal in Edward Brown Donohue an unusual capacity as a skilful organizer and a most competent executive—qualities which were later to be employed usefully in even greater efforts.

Immediately on the completion of the West Yellowstone duties, the engineering construction firms of Foley Brothers, Inc., and Spencer, White and Prentis, Inc., employed Mr. Donohue as highway engineer to take charge of the design and construction of highways in Iran near the Persian Gulf, which these firms (as joint venturers) were building for the United States Army

Engineers. By reason of the precarious state of his own health and the terrific climatic conditions in Persia, the Army physicians—and his own—refused to permit Mr. Donohue to leave for this overseas assignment.

In an advisory capacity, on special engineering investigation, he was employed by Foley Brothers, Inc., until April 24, 1942, at which time The Pleasantville Constructors (Foley Brothers, Inc., Spencer, White and Prentis, Inc., Winston Brothers Company, and W. E. Callahan Construction Company with their associates) engaged Mr. Donohue to accompany its party, with the Army engineers, on a preliminary visit to the proposed site of two large airfields which, together with buildings, water and sewer supply, and power installations, were to be built in Nassau, Bahamas, British West Indies, for the United States Government. Mr. Donohue remained in Nassau to establish local connections and to build a field office. Two weeks later he was appointed assistant general manager of the project. On January 7, 1943, he was promoted to general manager and remained in that capacity until the completion of the work late in December, 1943. His management of this project was outstanding and was obviously the high point of his career. The United States and British officials and the construction firms he represented outspokenly commended his work; the Duke of Windsor, Governor General of the Bahama Islands, who had formed a warm attachment for him, commended him personally for the diplomatic manner in which he handled the many perplexing, difficult problems affecting labor affairs and relations between American and British interests.

In Mr. Donohue, personal charm, sound engineering judgment, and business acumen were combined; wherever he went and whatever his position, he had a host of good and lasting friends; whatever his problem, he solved it with judgment. Standing six feet four inches—gaunt, lean, powerful looking—his was a commanding figure, yet one of modest carriage. As a public official his reputation for integrity was unblemished; in his career as a construction superintendent he demonstrated not only exceptional business judgment and technical knowledge but also the rare talent of diplomacy. Without exception his associates—in low places and in high position—commented on his kindness, complete sense of justice, and his courtly, gentlemanly character.

Strain, overwork, and impaired health caused his death on February 9, 1944, and terminated a brilliant engineering and construction career.

Edward Brown Donohue was forty-seven years old at the time of his death. He was married in 1926 to Gretchen Coates, who died in 1933, leaving two sons, Allan and George. In 1938 he was married to Kathleen McGrath of Butte, Mont., who survives him.

Mr. Donohue was elected an Associate Member of the American Society of Civil Engineers on April 20, 1925, and a Member on September 9, 1940.

MAX HARRY DOYNE, M. Am. Soc. C. E.[1]

Died August 1, 1943

Max Harry Doyne was born in New York, N. Y., on April 6, 1891, the eldest of the four children of Charles Doyne and Ida (Singer) Doyne. He received his early education in the public schools of New York City. From 1909 to 1911 he attended Cornell University at Ithaca, N. Y. He completed his engineering training by taking a night course at Cooper Union Institute in New York, from which he was graduated in 1915 with the degree of Bachelor of Science in Civil Engineering. In 1918 he received the degree of Civil Engineer from Cooper Union.

In August, 1916, after several years of junior engineering experience with New York engineers and architects, Mr. Doyne went to St. Louis Mo., as assistant engineer with C. E. Smith and Company, consulting engineers, becoming chief engineer and manager in 1928. In 1941 he was appointed Director of Public Utilities of the City of St. Louis by the Hon. William Dee Becker, then Mayor of St. Louis. On August 1, 1943, together with Mr. Becker and eight others, Max Harry Doyne met with an untimely death in a glider exhibition accident at Lambert Field in St. Louis.

Mr. Doyne made engineering studies and reports on passenger terminals for Montreal, Canada, and New Orleans, La., and on a Fruit and Produce Terminal for New Orleans. He prepared appraisals and valuations for several stockyard companies, for presentation before the U. S. Department of Agriculture. He was consultant to the City of St. Louis on matters before the Missouri Public Service Commission, involving rate of return of the various large utilities operating in St. Louis. He represented numerous short line railroads in federal valuation cases, appearing before the Interstate Commerce Commission. He was a formidable witness and always well prepared. In 1920–1922 he did the field work and assisted C. E. Smith, M. Am. Soc. C. E., in preparing a comprehensive report on the St. Louis-East St. Louis railroad terminals.

While Mr. Doyne was manager of C. E. Smith and Company, the firm prepared the designs and supervised the construction of all the recent railroad approaches to the St. Louis Municipal (Douglas MacArthur) Bridge. The firm also drew up all the construction plans for the new approaches to the McKinley Bridge at St. Louis. In addition, numerous new and reconstructed industrial plants were planned and constructed.

In 1936 and 1937, as consulting engineer for the Kaw Valley Drainage District, Kansas City, Kans., Mr. Doyne prepared the plans and supervised the raising of levees and the construction of concrete levee walls and slope revetments on the right bank of the Kaw River, thus providing flood protection for the industrial district at Kansas City.

---

[1] Memoir prepared by Samuel B. May, M. Am. Soc. C. E.

Mr. Doyne's professional experience was quite varied, covering surveys, designs, construction, special investigations, appraisals, reports, and city and regional planning problems. His construction experience covered many types of work, including municipal improvements, such as sewerage, water systems, streets, and flood protection; bridges; industrial buildings; railroads; and terminal facilities.

As Director of Public Utilities of the City of St. Louis, Mr. Doyne was very active in all matters under his jurisdiction. He arrived at his desk about 6 a.m. each day and stayed long after his staff had left. As chairman of the Airport Commission, he gave vigorous attention to the expansion of Lambert Airport and to the studies involving the acquisition by the city of an additional airport site. He likewise eagerly pursued the development of the "Jefferson National Expansion Memorial" on the St. Louis river front. He was chairman of the St. Louis Municipal Bridge Commission, a member of the St. Louis Defense Council, and Function Chief of the Utilities Division in charge of blackout preparation. All of these special assignments he handled capably, in addition to his numerous regular routine duties.

On June 21, 1915, Mr. Doyne was married to Rose Schneiderman of New York City. He is survived by his widow and a son, Morgan I. Doyne.

Max Harry Doyne was very active in various technical and fraternal groups, including—in addition to the Society—the American Railway Engineering Association, the American Water Works Association, St. Louis Institute of Consulting Engineers (past-president), the Engineers' Club of St. Louis, Jerome L. Goldman Post of the American Legion (past commander), the Society of Forty and Eight (past Chef de Gare), St. Louis Lodge No. 20, A. F. and A. M. (past master), Missouri Consistory No. 1, Ancient and Accepted Scottish Rite, and the St. Louis Chamber of Commerce.

Mr. Doyne was elected a Junior of the American Society of Civil Engineers on January 19, 1920; an Associate Member on June 6, 1921; and a Member on July 16, 1928.

SAMUEL MORRISON ELLSWORTH, M. Am. Soc. C. E.[1]

DIED AUGUST 13, 1944

Samuel Morrison Ellsworth, the son of George Gower and Helen (Morrison) Ellsworth, was born at Braintree, Mass., on January 4, 1895. After attending the local schools, he studied sanitary engineering at the Massachusetts Institute of Technology in Cambridge. He was graduated with the degree of Bachelor of Science in Sanitary Engineering in June, 1916.

Mr. Ellsworth's career in civil and sanitary engineering was broad in compass and steady in growth. His search for experience was purposefully directed toward the ultimate goal of establishing himself as a consultant in sanitary engineering. Only for a short time was his choice of work determined by lack of opportunity for suitable employment. Mr. Ellsworth preferred to overcome the obstacles that often beset the path of young engineers rather than to exchange his ambitions for the tenuous satisfaction of economic security in an available post. His years of apprenticeship included service with the Massachusetts Department of Public Health; the municipal sewerage authority of Rye, N. Y.; the North Jersey District Water Supply Commission; and three firms of consulting engineers—Weston and Sampson, Morris Knowles, Inc., and Metcalf and Eddy. Included in his experience were surveying and field studies, supervision of construction, preparation of preliminary as well as final designs for sanitary works, and responsibility for engineering investigations and reports of varied character. This portion of his career occupied twelve years during which he became familiar with the thinking and methods of some of the leaders of the profession, including Harrison P. Eddy,[2] Past-President, Am. Soc. C. E., and X. H. Goodnough,[3] Robert Spurr Weston,[4] and Morris Knowles,[5] Members, Am. Soc. C. E. These men were good masters under whom to learn and splendid exemplars of the service to society which Mr. Ellsworth wanted eventually to perform in his own right.

---

[1] Memoir prepared by Gordon M. Fair, M. Am. Soc. C. E.

When the United States entered World War I in 1917, Mr. Ellsworth first served the American Red Cross and U. S. Public Health Service on extra-cantonment sanitation. Later he joined the American Expeditionary Force, United States Army, being promoted from a private in the infantry to Second Lieutenant in water sanitation with the First Army and ultimately to area water inspector at the American Embarkation Center at Le Mans, France.

Characteristic of Mr. Ellsworth's steadfastness of purpose was his seizing upon the depression years of the early nineteen thirties to become a consulting engineer. Some months after an extended trip to Europe to study the latest developments in sanitary works abroad—while on leave of absence from the firm of Metcalf and Eddy—he started his consulting practice in Boston, Mass. This practice grew slowly but steadily and was devoted to investigations, reports, design, and supervision of construction of water supply and sewerage works for municipalities and industries in New England. Mr. Ellsworth's solution of the engineering problems involved was characterized by a ready grasp of the essentials, willingness to give adequate analysis, and directness of execution.

As the clouds of world-wide war gathered for a second time during his life, Mr. Ellsworth directed all his energies toward the design and construction of essential military installations. Either in his own name or in collaboration with others he became associated with engineering work for Camp Edwards, Mass.; Weymouth (Mass.) Lighter-than-Air Base; Naval Advance Base Depot at Davisville, R. I.; Camp McCain at Grenada, Miss.; the Holston Ordnance Works at Kingsport, Tenn.; and the Pratt and Whitney Works at East Hartford, Conn. Without giving concern to his own welfare, he devoted long hours to the completion of the tasks that were to become so important in the winning of the war. His untimely dealth may reasonably be traced to his failure properly to husband his strength during three years of continuous application to these problems.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 104 (1939), p. 1867.

[3] For memoir, *ibid.*, Vol. 101 (1936), p. 1565.

[4] For memoir, *ibid.*, Vol. 109 (1944), p. 1542.

[5] For memoir, *ibid.*, Vol. 98 (1933), p. 1567.

From his Pilgrim ancestors, Mr. Ellsworth inherited a rugged idealism which was linked to reality by a gentle sense of humor. This gave comfort to him as well as to those who sought his judgment on some of the perplexing social questions of the times. His interest in public affairs made him conscious, in particular, of the public responsibilities of the engineer. His own responsibilities he met with sincerity and integrity. He served the Town of Braintree as chairman of the Sewer Commission; the City of Boston as a member of the Works Projects Board; Harvard University, at Cambridge, as a lecturer on sanitary engineering design; and the federal government as a water consultant. In addition, Mr. Ellsworth held office in many of the engineering societies of which he was a member. He served as president of the Northeastern Section of the Society and of the New England Sewage Works Association, and was secretary of the New England Section of the American Water Works Association. When he died, he was president of the Boston Society of Civil Engineers and director-elect of the New England Water Works Association.

Mr. Ellsworth wrote a number of papers describing the engineering works that he constructed. Among his most thought-provoking writings, however, were those relating to the welfare of the engineering profession and a paper in which, well in advance of others, he raised the question of whether infantile paralysis could be spread by bathing in sewage-polluted waters.

Samuel Ellsworth was a true son of New England. As such he possessed rectitude of thought in full measure. However, he did not permit his thinking to be hampered by traditionalism. Instead he was willing to accept changing social practices as evolutionary in the American way of life. His friends will remember him for the stimulating arguments which he presented for keeping an open mind on important questions and for advancing the welfare of the profession of engineers as well as that of all men. Often he argued to clarify his own thinking on timely subjects. This fact he would wistfully acknowledge if forced to do so—a trait that endeared him to his listeners.

Mr. Ellsworth was a lover of good music and an accomplished violinist. In professional and social contacts he possessed the rare ability to find something in the character or behavior of most persons which he could admire and through which he could reach a common meeting ground. In consequence he was respected by simple folk as well as by more broadly educated people. He had quarrels as do all men who feel deeply and are honestly outspoken; but his disputes were directed toward the exposure of shallow and dishonest thinking or thoughtless acts. In this he manifested an urge for reforming people and circumstances—a vestige probably of his descent from a long line of teachers and preachers.

His death, on the threshold of the years during which he might have made his engineering ability and personal force felt more widely, has deprived the profession of a man who represented the finest in engineers and his friends of a wise counselor and congenial companion.

On November 6, 1926, Samuel Ellsworth contracted a happy marriage with Marjorie Ann Thomas of Summit, N. J. He is survived by his widow, together with two sons, Samuel Morrison, Jr., and Thomas Allen.

Mr. Ellsworth was elected an Associate Member of the American Society of Civil Engineers on September 10, 1923, and a Member on April 15, 1929.

FRANK HARVEY ENO, M. Am. Soc. C. E.[1]

Died August 7, 1943

Frank Harvey Eno was born in Elmwood, Ill., on July 27, 1865, the eldest of the three sons of Harvey Eno and Cecilia (Kellog) Eno. His father was a farmer and schoolteacher, and Frank spent his first ten years on a farm. In 1875, because of poor health, his father moved to Pomona, Calif.

After graduation from high school, he entered the University of Southern California at Los Angeles where he studied for two years. In the meantime he had become interested in civil engineering by watching the construction of a railroad through his home town of Pomona. Since, at that time, there were no engineering courses at the University of Southern California, he returned to his native state, entered the University of Illinois at Urbana in 1887, and was graduated with the degree of Bachelor of Science in 1891.

During the summer vacations between his sophomore and junior and his junior and senior years he worked as a rodman and instrumentman for Cole, Alvord and Shields of Chicago, Ill., on street, subdivision, and sewer work in the Burchwood subdivision, later a part of Chicago.

Immediately after graduation he went to work for the World's Columbian Exposition Company at Chicago, as first assistant engineer in the water supply and sewerage department. He later became superintendent of the Department of Water Supply, Sewerage and Fire Protection at the Exposition. Based on this experience, he prepared a thesis in partial fulfilment of the requirements for the professional degree of Civil Engineer, which he received from the University of Illinois in 1894. When the Exposition was closed, Mr. Eno became assistant engineer for John A. Cole, consulting engineer of Chicago. From 1895 to 1898 he was Superintendent of Public Works and Village Engineer for Winnetka, Ill. In 1898 he was employed by the City Engineer's office in Columbus, Ohio, as assistant engineer and chief draftsman. In this capacity he supervised the preparation of maps and plans for the new city water supply and storage dam on the Scioto River and for the street and drainage problems of the city.

---

[1] Memoir prepared by a Committee of the Central Ohio Section consisting of Clyde T. Morris, M. Am. Soc. C. E., Chairman, and C. W. Allen, Assoc. M. Am. Soc. C. E., and C. B. Hoover, M. Am. Soc. C. E.

After the death in 1902 of C. N. Brown, who had been head of the Civil Engineering Department at Ohio State University in Columbus, Mr. Eno was appointed Associate Professor of Civil Engineering. In 1905 he was promoted to Professor of Municipal and Sanitary Engineering, and in 1926 he was made Research Professor of Highway Engineering, continuing in this position until his retirement in 1935.

In addition to his professorial duties, Professor Eno was active in civic affairs and local and national engineering organizations. He was a charter member of, and served for ten years on, the City Planning Commission of Columbus. For two years he was chairman of the Highway Research Board of the National Research Council. He also served as governor of the Ohio Good Roads Federation and as director of the Ohio Highway Research Board. He belonged to the Society for the Promotion of Engineering Education, Sigma Xi fraternity, the Engineers' Club of Columbus, and the Faculty Club.

In 1890, Professor Eno was married to Nellie C. Kellogg, who continued as his constant companion and loyal helpmate until his death. He is survived by his widow, and one brother, Imle L. Eno.

Professor Eno was active in the organization of the Central Ohio Section of the Society and served as its first president in 1921–1922. The Section suffers a deep sense of loss in the death of Frank Harvey Eno. We knew him as an excellent teacher, an engineer of wide experience, an enthusiastic investigator, a loyal friend, and a true Christian gentleman. He possessed the unqualified confidence of his colleagues. He never hesitated where right and justice were involved, possessing that rare quality of saying the gracious thing and always thinking kindly of those with whom he might disagree.

Professor Eno was elected a Member of the American Society of Civil Engineers on March 4, 1903. He became a Life Member in 1936.

FREDERIC HAROLD FAY, M. Am. Soc. C. E.[1]

DIED JUNE 5, 1944

Frederic Harold Fay was born in Marlboro, Mass., on July 5, 1872, the only child of John Sawyer Fay and Elizabeth (Ingalls) Fay. He was a direct descendant (eighth generation) of John Fay who was born in England in 1648, sailed from England on the *Speedwell,* landed in the Massachusetts Bay Colony on June 27, 1656, and settled in Marlboro. John Fay participated in King Philip's War. Elizabeth Ingalls was a descendant (ninth generation) of Edmund Ingalls who came from England in 1629 and settled in Lynn, Mass.

John Sawyer Fay was a veteran of the Civil War who lost a hand and a leg in battle, and, while in a field hospital, was captured by the Confederates and confined in Libby Prison in Richmond, Va. He once made an interesting Memorial Day address at Marlboro describing his experiences after receiving his wounds and while in Libby Prison. He had the distinction of having been appointed postmaster of Marlboro by every president from Andrew Johnson, in 1865, to Theodore Roosevelt with the exception of James A. Garfield who died before Mr. Fay's term of office expired. He occupied this position for forty-nine years until his death in 1914, during which time the post office was raised from a fourth-class post office to a second-class post office. He was also a vice-commander of the Massachusetts Department of the Grand Army of the Republic.

---

[1] Memoir prepared by C. M. Spofford, M. Am. Soc. C. E.

Frederic Fay, after his education by private instructors and in the public schools of Marlboro, entered the Massachusetts Institute of Technology at Boston in 1889 and received the degrees of Bachelor of Science in Civil Engineering in 1893 and Master of Science in Civil Engineering in 1894, being the first man to receive the degree of Master of Science in Civil Engineering from that institution.

Prior to his graduation, he served as a transitman for the city engineer of Marlboro and, after graduation, was employed for a brief time by the Boston Bridge Works. In February, 1895, he entered the Engineering Department of the City of Boston as draftsman and later became assistant engineer in charge of design and construction of the city's bridges and of waterfront developments. After the death of William Jackson,[2] M. Am. Soc. C. E., then city engineer, Mr. Fay assisted in the development of the plan for the consolidation of the engineering, street, and water departments of Boston into a Department of Public Works, and in July, 1911, he was appointed division engineer in charge of the Bridge and Ferry Division of that department. Under this division were placed the design, construction, maintenance, and operation of the municipal bridges and ferries and also the abolition of grade crossings and the general engineering work formerly done by the city engineer. In addition, Mr. Fay was made the commissioner representing Boston on the Boston and Cambridge Bridge Commission. During this period as an associate of John E. Cheney,[3] M. Am. Soc. C. E., and also acting independently, he served as consultant on sundry bridge and structural engineering projects and acted as expert in legal cases.

In 1914 he resigned his position with the city and, in association with the writer and Sturgis H. Thorndike,[4] M. Am. Soc. C. E., organized the engineering firm of Fay, Spofford and Thorndike. This firm (in whose operations he played a leading part until a few months before his death) made numerous engineering and economic reports on various undertakings, and it also designed and gave engineering supervision during construction to many government, state, municipal, and private projects, including army bases, bridges, airfields, harbor works, industrial buildings, sewerage, and water works systems. Among the more important of these projects were the Boston Army Supply Base, built during World War I; the Bourne and Sagamore bridges across the Cape Cod (Massachusetts) Canal, for the former of which the firm received the award of the American Institute of Steel Construction for the most beautiful bridge built at a cost of more than $1,000,000 in 1934; a bridge across Lake Champlain, which received a Phebe Hobson Fowler Architectural-Engineering Award in 1930; the Hampden County Memorial Bridge at Springfield, Mass.; the State Pier at Portland, Me.; the water works system of Warwick, R. I.; and the sewer system and sewage treatment works of Cranston, R. I. During 1941–1944, the firm was the engineer member of the architect-engineer organization which designed fifteen northern North American and off-continent bases for the U. S. War Department, and during this same period was associated with other engineering firms under the title of Dry Dock Engineers, which organization designed numerous dry docks and other harbor works for the U. S. Navy Department.

[3] For memoir, *ibid.*, Vol. LIX (December, 1907), p. 537.

[4] For memoir, *ibid.*, Vol. 93 (1929), p. 1910.

Following Mr. Fay's resignation from the Boston Bridge and Ferry Division, he continued actively in civic affairs and served for many years as member and chairman of the Boston City Planning Board, chairman of the Boston Board of Zoning Adjustment from its establishment, member of the Special Committee to Investigate Boston Intermediate Thoroughfares, member of the Boston Advisory Commission on Building Heights, and member of the Special Commission on Fort Point Channel. He also served as vice-president and director of the Boston Chamber of Commerce and for many years was chairman of the Committee on Municipal and Metropolitan Affairs. Mr. Fay always retained much interest in the activities of the Massachusetts Institute of Technology, serving at one time as president of its alumni association and later as alumni member of its Corporation. The class of 1893, of which he was a member, participated ardently for many years in Technology affairs—for which Mr. Fay, as secretary of the class from its graduation, was largely responsible. The class history, which he prepared on the occasion of the class reunion in 1923, was a notable example of class literature. Mr. Fay's death occurred exactly one year after the class had celebrated its fiftieth anniversary.

To the engineering profession at large Mr. Fay gave valuable service as a director and a member of numerous committees of the Society, as president of the American Institute of Consulting Engineers and member of its council, as president of the Boston Society of Civil Engineers, and as director and vice-president of the Society of Terminal Engineers. He was also a member of the New England Water Works Association, the Permanent International Association of Navigation Congresses, the Engineering Society of Western Massachusetts, the Engineering Institute of Canada, the American Concrete Institute, and the Massachusetts Highway Association. His scientific societies included the American Academy of Arts and Sciences and the American Association for the Advancement of Science.

Mr. Fay was the author of numerous papers and articles appearing in the publications of the Society,[5] the Boston Society of Civil Engineers,[6] and *The*

Technology Review (Massachusetts Institute of Technology),[7] and elsewhere.[8] He presented many addresses to various societies dealing with engineering, transportation, and city planning matters. The memorial volume "Fifty Years of Boston" contained an article by him entitled "The Planning of a City." He was also the author of "The Population and Finances of Boston."[9]

During much of his life Mr. Fay gave considerable time to the work of the American Unitarian Association, and served as vice-president of the Unitarian Laymen's League and as chairman of the board of trustees of the First Parish Church in Dorchester, Mass.

He was a member for many years of Northeastern University (Boston) Corporation, and served on its board of trustees and on its executive committee. He was also chairman of its committee on buildings.

His clubs at the time of his death were The Union Club of Boston, The Engineers Club of Boston, The Engineers Club of New York, and The Technology Club of New York.

Mr. Fay had many qualities to insure success. His physical strength during his prime enabled him to work longer and more intensely than most men. He took nothing for granted, investigated thoroughly everything he undertook, and had the vision to foresee the important factors that would affect any problem under his consideration. His public spiritedness is shown by his numerous civic activities, and in his private life he was ever mindful of the welfare of his family, associates, and employees and gave generously of his time and energy to all who came to him for advice.

On April 21, 1897, at Quincy, Ill., Mr. Fay was married to Clara May Potter, a descendant of a Massachusetts family then living in Illinois. Mrs. Fay at one time was a prominent member of the Daughters of the American Revolution. Mr. Fay is survived by his widow; five daughters, Beatrice (Mrs. Frederic B. West), Mildred Elizabeth (Mrs. Robert S. Boland), Dorothy Clara (Mrs. Joseph Finestein), Eleanor Potter (Mrs. Wentworth Kennard), and Elizabeth Fay; and five grandchildren, Peter, Richard, and Fay Boland, and Joan and Dwight Kennard. A son, Allen Potter, died at the age of eight.

Mr. Fay was elected a Junior of the American Society of Civil Engineers on October 2, 1894; an Associate Member on April 2, 1902; and a Member on January 5, 1904.

EDWIN STANTON FICKES, M. Am. Soc. C. E.[1]

DIED DECEMBER 19, 1943

The industrial age has brought into prominence a new type of executive —one possessing not only the essential qualifications for leadership that have always brought men to the top throughout the world's history but also a keen sense of the great importance of sound economics, engineering, and thorough research. Mr. Fickes was such a man. His whole mature life was closely associated with the remarkable growth of the aluminum industry, and he helped to establish many of the markers reached and passed by that industry in its unbroken march of progress.

Edwin Stanton Fickes, the son of George Jackson and Mary (Akin) Fickes, was born at Steubenville, Ohio, on November 3, 1872. His early education was obtained in the public schools of that city. In 1894 he was graduated with the degree of Civil Engineer from Rensselaer Polytechnic Institute at Troy, N. Y. During the summer vacation of 1892, he began his engineering career as a masonry inspector for the Pittsburgh, Cincinnati, Chicago and St. Louis Railroad Company. After graduation, he was employed from July, 1894, to October, 1895, by the late William Glyde Wilkins,[2] M. Am. Soc. C. E., and the late George S. Davison, Past-President and Hon. M. Am. Soc. C. E., consulting engineers of Pittsburgh, Pa., on the design and construction of water works, coal handling works, and bridges. From October, 1895, to January, 1896, he was engaged on surveys for Gustave Kaufman,[3] M. Am. Soc. C. E., of Pittsburgh. From January, 1896, to February, 1897, he was an assistant to Hermann Laub,[4] Assoc. M. Am. Soc. C. E., consulting engineer of Pittsburgh, on construction of highway bridges and manufacturing plants. From February, 1897, to January, 1899, he was again employed by Wilkins and Davison on the design of water works. From January to October, 1899, he worked for the Metropolitan Street Railway of New York, N. Y. During these years he was also identified with estimates and design of power stations, ore docks, and street railways for São Paulo, Brazil; Sidney, Nova Scotia, Canada; Georgetown, British Guiana; Havana, Cuba; and Paris, France.

In October, 1899, Mr. Fickes began his association with The Pittsburgh Reduction Company, shortly thereafter becoming its chief engineer. His initial work with that company was on the design of new plant buildings being constructed at Niagara Falls, N. Y. About 1900 a subsidiary company was organized for the manufacture of aluminum in Canada at Shawinigan Falls, Quebec. Mr. Fickes planned and superintended the construction of the plant. During the next two years a number of plant expansions at New Kensington,

---

[1] Memoir prepared by a Committee of the Pittsburgh Section consisting of Robert F. Ewald, F. W. Ely, and Myron W. Hanson, Members, Am. Soc. C. E.

Pa., Niagara Falls, and Shawinigan Falls occupied much of his time. He also gathered data which led in 1901 to the beginning of bauxite mining operations in Arkansas and to the construction of a plant for the manufacture of alumina at East St. Louis, Ill. In 1902 under Mr. Fickes' guidance the first aluminum producing furnaces were built at the great Massena (N. Y.) works.

The period from 1905 to 1907 was one of exceptional activity and expansion. During that time The Pittsburgh Reduction Company adopted the policy of developing its own hydroelectric power and began by taking over the plant of the St. Lawrence Power Company at Massena, which was in financial difficulties. As chief engineer of The Pittsburgh Reduction Company, Mr. Fickes was prominent in all these activities. In addition, he took charge of the purchasing department in 1901, the operations of the American Bauxite Company and direction of all rail and ocean traffic in 1907, and the operation of the alumina plant at East St. Louis in 1909.

The officials of The Pittsburgh Reduction Company early realized the possibilities in developing the Long Sault Rapids of the St. Lawrence River as a source of energy for the manufacture of aluminum. In 1906 the company started an active campaign to purchase property, to secure engineering data, and to prepare the necessary plans. All this work was under the jurisdiction of Mr. Fickes. The campaign continued for years until it became evident that the project could not be completed because of conflicting political interests.

In 1907 The Pittsburgh Reduction Company became the Aluminum Company of America, and in the same year Mr. Fickes made the first of many trips to Europe. During the period from 1907 to 1910, he was very busy on a wide expansion program to better existing facilities, personally suggesting and directing a number of marked improvements in the Bayer process of alumina manufacture. In addition, he was active in the search for new sources of bauxite in various parts of the world. It became evident about 1910 that the company would be unable to bring into harmony the many conflicting interests involved in the development of the Long Sault Rapids. A search was begun for other hydro power, and as an initial step in the development of such sources a number of smaller developments were constructed in northern New York, the power being transmitted to Massena. About the same time the Aluminum Company of America became interested in a number of hydro sites on the Little Tennessee River and in 1913 erected its first southern aluminum plant at Alcoa, Tenn., near Knoxville, the first block of power being taken from the Tennessee Electric Company, which was then building a series of plants on the headwaters of the Tennessee River. In addition to these activities, Mr. Fickes also devoted much personal effort to locating new supplies of bauxite in the United States, Europe, and South America. His investigations finally took him to South America in the latter part of 1913, when he realized that a very large proportion of the company's future supplies would come from the Guianas. Steps were immediately taken to acquire and develop necessary properties. The first South American ore was shipped to the United States in 1918.

In 1915 the Aluminum Company of America purchased the holdings of the Southern Aluminium Company, a French company, which had been building a hydroelectric development and aluminum plant on the Yadkin River at Badin, N. C., and had been compelled to drop the project at the beginning of World War I. Mr. Fickes was instrumental in the development of new plans for the aluminum plant. Much work done by the French Company was scrapped, and the plant was constructed at a different site.

In the latter part of 1916 Mr. Fickes took a long trip through Russia, Siberia, and Japan, studying the possibilities for the development of aluminum industries in those countries. In 1918 he brought into reality a project that had long been in the back of his mind—the organization and development of a capable research department. This department soon became a leader in the development of strong aluminum alloys and methods in the manufacture and application of aluminum in all its forms, as well as in research in scores of allied fields. In 1919 Mr. Fickes became a vice-president of the Aluminum Company of America.

From the close of World War I until the latter part of 1925, Mr. Fickes' activities were primarily connected with improvements at the company's existing plants and the development of the bauxite mines in the Guianas. He made a number of trips to Europe in his ceaseless search for new and improved methods. The principal new development of this period was the construction and placing in operation, in 1920, of the first units of the great aluminum rolling mills at Alcoa. In 1924 Mr. Fickes was placed in full charge of all the company's research activities.

A new upsurgence in the growth of the aluminum industry in America took place in 1924 when the Aluminum Company of America began the construction of its Santeetlah hydroelectric development in the Little Tennessee watershed in North Carolina. In 1925 the company became interested in the hydroelectric development of the Saguenay River in Quebec, Canada, and built the first units of the aluminum plant at Arvida, Quebec, Canada—later the greatest in the world. In 1927 construction was started on the third hydroelectric development on the Yadkin River in North Carolina (High Rock). In the same year the company began to build Chute à Caron Dam on the Saguenay River—the first step in what has become the world's greatest single hydroelectric power station—namely, Shipshaw, with 1,200,000 hp under one roof. In 1928 construction began on Calderwood, the third of five hydroelectric developments built by the company on the Little Tennessee River. As head of the Aluminum Company's engineering division, Mr. Fickes had a very active part in all these works. In 1929 he became a director of the company and in 1931 senior vice-president. The economic depression, which began early in 1930, ended all major expansion and not until 1937 was any new work, beyond minor additions to existing facilities, attempted. In that year a new fabricating plant was built at Lafayette, Ind., a new foundry and forge shop at Vernon, a suburb of Los Angeles, Calif., and a new alumina plant at Mobile, Ala.

In recognition of his great services in promoting high standards of engineering and his interest in research on problems connected with the manufacture and use of aluminum and the development of important improvements in those processes, Rensselaer Polytechnic Institute conferred the honorary degree of Doctor of Engineering on Mr. Fickes in 1936. This event was the culmination of a long unbroken career in engineering achievements.

In 1937 his health began to fail. Mr. Fickes then resigned from all his offices and retired to a life of relative quiet in Washington, Conn., and Annapolis Royal, Nova Scotia, Canada, with winter sojourns in California. After his retirement from active duties he served the Office of Production Management as a special adviser.

On April 10, 1909, Mr. Fickes was married to Marguerite Webb, of Warwick, N. Y. Their children are: Harriet Webb (Mrs. Donald W. Chadwick), George J., and Charles W.

His principal hobbies were the collection of etchings and of books and manuscripts relating to American history previous to 1860. He was also greatly interested in art, architecture, gardening, and music, and was a director on the board of the Pittsburgh Symphony Orchestra until his retirement. His beautiful home on Woodlawn Road in Pittsburgh, the scene of his gardening activities, was given to the Pennsylvania College for Women at Pittsburgh after his retirement.

Mr. Fickes possessed a quiet but very forceful personality and an exceptionally well-developed sense of the practicability of any project, large or small. He was especially appreciative of the importance of research and the application of sound engineering principles. Much of the success of the Aluminum Company can be attributed to his strict adherence to the principles of thorough research and sound engineering and construction. His extensive travels placed him in close touch with the leaders in the aluminum industry throughout the world and his keen insight into the details of the almost innumerable ramifications of that business was the marvel of all those who knew him well. No one took a greater and livelier interest in anything that affected the usefulness of aluminum or in the scores of materials and endless variety of equipment required in its production.

He was a member of the American Institute of Mining and Metallurgical Engineers, Rensselaer Society of Engineers, American Association for the Advancement of Science, Historical Society of Western Pennsylvania, American Federation of Arts, University Club of New York, Engineers Society of Western Pennsylvania, Caxton Club of Chicago, Quivera Society of Albuquerque, N. Mex., Sigma Xi, and Engineers Club of New York. Until his retirement in 1937, he had been on the Metallurgical Advisory Board of Carnegie Institute of Technology at Pittsburgh. He also belonged to Duquesne Club, Junta Club, University Club, and Fox Chapel Country Club—all of Pittsburgh.

Mr. Fickes was elected a Junior of the American Society of Civil Engineers on January 4, 1898; an Associate Member on February 6, 1901; and a Member on December 6, 1904.

HAROLD CHAMBERLAYNE FISKE, M. Am. Soc. C. E.[1]

DIED JANUARY 8, 1942

Only too often does genius, because of innate modesty, fail to receive due recognition until after death. This is true in the case of Harold Chamberlayne Fiske, Colonel, Corps of Engineers, U. S. Army, whose vision and undaunted spirit, in the face of what at the time seemed insuperable obstacles, led the way to the comprehensive development of the larger river systems of the United States for power production, navigability, and abatement of flood damage. What had long been regarded by engineers and legislators as mere wishful thinking was shown by him to be practicable. Quoting the *Chattanooga Times* of January 9, 1942: "* * * in a large sense the Tennessee Valley program and public power in this region are monuments to his [Colonel Fiske's] foresight." It remained for others to mature the plan, to provide the necessary legislation, and to build. It seems appropriate to recount briefly, with due regard to historic accuracy, Colonel Fiske's contribution to engineering progress and his military achievements, for Colonel Fiske was a resourceful and gallant soldier with an excellent war record known to but few.

Harold Chamberlayne Fiske was born on March 1, 1880, at Jamestown, N. Y. He attended Union College in Schenectady, N. Y., from September, 1897, to June, 1899. He then went to the United States Military Academy at West Point, N. Y., being graduated as a Second Lieutenant, Corps of Engineers, U. S. Army, on June 11, 1903, ranking third top man in his class. (Among his classmates were such officers as Gen. Douglas MacArthur; Maj. Gen. Julian L. Schley (retired), M. Am. Soc. C. E.; Maj. Gen. Ulysses S. Grant, III, Assoc. M. Am. Soc. C. E.; Maj. Gen. R. C. Moore; Brig. Gen. Max C. Tyler, M. Am. Soc. C. E.; the late Brig. Gen. Hugh L. Johnson; and Maj. Charles T. Leeds (retired), M. Am. Soc. C. E.)

On October 8, 1910, he was married to Mary Mitchell, the sister of the late Col. Americus Mitchell and of the late Gen. William A. Mitchell. First Lieutenant Fiske and Miss Mitchell were the first couple to wed in a formal ceremony in the then newly finished West Point Chapel. Colonel Fiske is survived by his widow; by a daughter, Rebecca A. (Mrs. Saint Julien Fiske Marshall); and by two granddaughters, Louise and Virginia Marshall.

At the age of twenty three, immediately following graduation, Second Lieutenant Fiske was sent to the Philippines in charge of land surveys, bridge construction, and the extension of the Jolo harbor jetty. He was promoted to First Lieutenant on April 23, 1904. After a year of postgraduate work (1905–1906) at the Engineer School, Washington Barracks, Washington, D. C., he spent a year in Cuba, making extended reconnaissances for railroad bridges, and in immediate charge of building construction of public works (Obras Publicas) for Cuba. This was followed by additional postgraduate work and by military surveys of Staten Island, New York, in command of a company of engineer troops on both garrison and field duty. From August, 1908, to August, 1912, he taught at West Point Military Academy, first as instructor and later as assistant professor of civil and military engineering. He was promoted to Captain on February 27, 1911.

---

[1] Memoir prepared by Gerard H. Matthes, Hon M. Am. Soc. C. E.

From August 12, 1912, to October 19, 1915, Captain Fiske was assigned to river and harbor work in the United States, first as assistant to the district engineer (and for six months with the title of acting district engineer) at the U. S. Engineer Office at Pittsburgh, Pa., on construction and repairs of locks and dams of the Ohio, Monongahela, and Allegheny rivers. This was followed by a tour of duty as district engineer at the U. S. Engineer Office in Vicksburg, Miss., from October, 1915, to June, 1917. He was promoted on January 12, 1916, to the rank of Major. At Vicksburg, Major Fiske's principal work was on the construction and maintenance of revetments and levees and on channel dredging operations on the Red and Yazoo rivers, tributaries of the Mississippi River. In the five years preceding World War I, he developed a profound interest in the potentialities of commercial river navigation and the potentialities, also, of flood control. The latter field, then in its infancy, had been brought into focus during this period by the passage of the Conservancy Act of Ohio in 1914 and by the first Flood Control Act passed by Congress in 1917, covering the Sacramento and Mississippi rivers. Major Fiske's interest and studies in these two directions were interrupted in 1917 by the entrance of the United States into World War I.

In June, 1917, he was placed in command of the First Battalion, First Engineer Regiment. His first task was the training of engineer troops at Washington Barracks for war service. Promoted to Lieutenant Colonel (temporary) on August 5, 1917, he arrived in France with the first engineer regiment on August 22, 1917, and immediately began organizing the Army Corps engineer training school which he conducted as its director until February, 1918. On December 20, 1917, he was promoted to the rank of Colonel (temporary). Colonel Fiske saw active service as Commanding Officer of the One Hundred and Seventh Engineer Regiment of the Thirty-Second Division overseas, in the Advance Section from February, 1918, to January, 1919. During the period of the regiment's most active operations, in the course of which it took part in four offensives, Colonel Fiske's work as division engineer elicited the highest commendation from his superior officers. His accomplishments are summarized in a letter from Maj. Gen. W. G. Haan, U. S. Army, commanding the Seventh Army Corps, dated December 10, 1918, addressed to the Commander in Chief of the American Expeditionary Forces, in which he recommended Colonel Fiske for award of the Distinguished Service Medal (which was never made), stating that he had earned it for:

> "* * * engineering work of the highest character accomplished during the active operations of the Division and particularly in the following actions:
>
> "(*a*) Second Battle of the Marne, July 29–Aug. 7, while the Division was serving with the 6th French Army.
>
> "(*b*) Near Soissons, Aug. 30–Sept. 5, while the Division was serving with the 10th French Army.

"(*c*) In the vicinity of Romagne, Northwest of Verdun, Sept. 29–Oct. 20, where the Division was serving with the First American Army.

"2. During these operations and during the periods of preparation for battle, Colonel Fiske showed an unusual knowledge and insight into the Engineering requirements for the battles, and his plans for accomplishing results were always of the most satisfactory kind, and in executing these plans during the actions the work of himself and his Regiment was tireless, and totally disregarded danger in working near the front lines. Colonel Fiske himself was constantly directing these operations and saw that the plans of the Division Commander for keeping roads in order and other Engineering operations up to date were fully and completely carried out.

"3. In actually accomplishing useful work during battle and in preparation before battle, I consider Colonel Fiske has shown himself to be one of the most useful and accomplished Engineer officers we have in France, and never lost an opportunity in having his work in full preparation, whether that required night work or not.

"4. I consider that Colonel Fiske has fully earned the award of the Distinguished Service Medal, and more, if more could be given him."

For service in World War I, he was made an Officer of the Legion of Honor of France, received the Croix de Guerre and the Victory Medal, and was awarded the Order of the Purple Heart. Colonel Fiske, on April 19, 1919, was awarded a citation by Gen. John J. Pershing, Commander in Chief of the American Expeditionary Forces, as an expression of appreciation of his services as division engineer, Thirty-Second Division. After November 11, 1918, Colonel Fiske served as Corps Engineer of the Third Corps, Third Army, in its march to and across the Rhine River and in its operations in the occupied sector, east of the Rhine until July, 1919, when the Corps was disbanded. The crossing of the Rhine at Hönningen, Germany, on May 9, 1919, was a remarkable feat in ponton-bridge construction, performed in 2 hr and 25 min across this deep and swift river at a point where it was 1,440 ft wide. Infantry and artillery passed safely over the bridge immediately upon its completion.

Upon his return from France, and having reverted to his permanent rank of Major, Corps of Engineers, U. S. Army, on August 19, 1919, he was reassigned in September, 1919, to river and harbor work as district engineer at Chattanooga, Tenn. For about two years Major Fiske served also as district engineer for the Nashville (Tenn.) District, until relieved by Maj. Julian L. Schley. In this dual capacity, he had charge of the operation and maintenance of locks and dams and of channel improvements on the Tennessee and Cumberland rivers. In 1920 he began the "Survey of the Tennessee River and Tributaries," ordered by Congress — the first study of a river system to be undertaken by the Corps of Engineers, in which the development of hydroelectric power and the control of floods were made integral parts of the plan for the development of navigation. Because of the remarkable potentialities of Major Fiske's plan, the rather strictly observed rule, which limits the tour of duty of officers of the Corps of Engineers at any one place not to exceed four years, was extended, and he continued to serve as district engineer at Chattanooga until November, 1926, his total incumbency at that post covering a little more than seven years. In permitting the extension, the War Department acceded to insistent requests from local authorities to keep Major Fiske at Chattanooga.

Before leaving Chattanooga, Major Fiske was promoted, on September 22, 1926, to the permanent rank of Lieutenant Colonel, Corps of Engineers, U. S. Army. He was placed in command of the Sixth Regiment of Engineers at Fort Lewis, Wash., in November, 1926, continuing in command of this regiment after it was moved to Fort Lawton, Wash. On June 15, 1930, he was retired upon his own application, having served continuously for thirty years in the Corps of Engineers, and, on June 21, 1930, he was designated Colonel, retired.

However, until January, 1933, Colonel Fiske was active as division engineer in charge of the Personnel Division of the Board of Transportation of New York, N. Y., assisting the late Col. J. R. Slattery,[2] M. Am. Soc. C. E., on the construction of the Eighth Avenue Subway, a difficult position for which, by reason of his extensive experience in handling men, he proved eminently fitted.

Retiring from active life, Colonel Fiske returned to Chattanooga to make his home in pleasant surroundings on Missionary Ridge. He continued to take a keen interest in the development of the Tennessee River Valley, serving as chairman of the Electric Power Board of Chattanooga until June, 1938, when he retired from active work on account of heart trouble and moved to Long Island, New York, in 1940, where he bought a home at Manhasset. He died there on January 8, 1942, from a heart attack induced by intense worry over his friend and classmate, Gen. Douglas MacArthur, at that time in great peril at Corregidor, in the Philippine Islands.

Colonel Fiske was active in engineering circles. He was a past-president (1929) of the Western Washington Section of the Society, and of the Seattle Chapter, Society of American Military Engineers; an honorary member and past-president of the Chattanooga Engineers Club; an honorary member of the Kiwanis Club of Chattanooga; and a member of the International City Managers' Association, the Army and Navy Club of Washington, D. C., and the Engineers Club of New York City.

Colonel Fiske was known to his associates as a modest man who was scrupulously honest with all with whom he came in contact, as well as with himself. His clear-thinking mind, genial personality, and resourcefulness won him the admiration of all his personnel.

Major Fiske's plan for the Tennessee River which contemplated coordinating the improvement of navigation with hydroelectric power development, flood peak reduction, and wider utilization of Tennessee's mineral resources met at first with both criticism and hearty approval. Criticism mostly came from officialdom which held that the Corps of Engineers under then existing statutes was concerned neither with power production nor with the abatement of flood damage. The power interests were skeptical—some of their engineers freely declared that it was inconceivable to them how navigation dams could be of value for power production. Convinced that his plan was technically as well as economically sound, Major Fiske continued his surveys and studies and eventually overcame many of the doubts which had been expressed as to the practicability of his plan. He urged substituting for the proposed project (specifying thirty-two low dams with small locks designed to make the Tennessee River navigable as far upstream as Knoxville for barges drawing only 6 ft) six power dams in addition to the then existing power dam at Hales Bar and the Muscle Shoals dam which was under construction. Thus, a navigable depth could be provided for the 9-ft draft which at that time had become standard for the Ohio and Mississippi rivers. Major Fiske further proposed that the cost of constructing the dams and the power plants be borne by power companies although the federal government was to assume the cost of constructing the locks and other navigation improvements. His plan also embraced the tributaries. Among the more important reservoir sites covered in his surveys were the Cove Creek site (later Norris Dam) on the Clinch River, where storage capacity sufficient to double the low-water flow and hence the primary power at the main river dams could be provided. He stressed the importance of water power development as necessary to the economic and industrial welfare of the Tennessee River Valley, and the material flood-stage reductions which would result from the operation of the storage dams were considered by him as an incidental although a profitable by-product. His early reports dated January 15, 1921, and March 15, 1922,[3] give evidence of Major Fiske's remarkably broad conception and sound vision. The power interests found his plan practical and far from visionary. In 1923, when his surveys had reached an advanced stage, the power companies had filed with the Federal Power Commission under the then new Federal Power Act, applications for permits to build dams and power plants at all the sites recommended by Major Fiske, totaling 1,500,000 hp of installed capacity. In an occasional instance more than one power company made application for the same site.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 99 (1934), p. 1511.

Another valuable contribution to engineering progress was made by Major Fiske in the course of the Tennessee River survey by the introduction of aerial photographic mapping. His survey was the first instance of an extensive river or harbor project in the United States being mapped by this method. This, together with his undaunted request for more than half a million dollars for making his studies and surveys—a sum unheard of in those days for a river survey by the Corps of Engineers—was typical of his courage in breaking away from established precedents. Although the aerial survey, followed by sketching contours on photographs by the plane-table method, was executed by personnel entirely new at these arts, acceptable results were produced, and time and money were saved. Congress was not accustomed to appropriating a half million dollars for river studies but became convinced of the merit of the project and made the funds available.

During a two-day hearing on the findings of the Tennessee River Survey before the House Committee on Rivers and Harbors (Sixty-Eighth Congress, First Session, March 31 and April 1, 1924), after a thorough discussion, one committee member referred to Major Fiske's plan as "astounding and amazing," and at this session the suggestion was first made that similar surveys should be instituted on other rivers of the United States. As a result, the River and Harbor Act of March 3, 1925, in Section 3, authorized and directed the Secretary of War, through the Corps of Engineers, United States Army, and the Federal Power Commission jointly:

---

[3] *House Doc. No. 319,* 67th Cong., 2d Session.

> "* * * to prepare and submit to Congress an estimate of the cost of making such examinations, surveys, or other investigations, as in their opinion, may be required of those navigable streams of the United States, and their tributaries, whereon power development appears feasible and practicable, with a view to the formulation of general plans for the most effective improvement of such streams for the purposes of navigation and the prosecution of such improvement in combination with the most efficient development of the potential water power, the control of floods, and the needs of irrigation."

There followed that historic instrument known as "House Document 308, 69th Congress, 1st Session" signed by Maj. Gen. H. Taylor, Chief of Engineers, and O. C. Merrill, M. Am. Soc. C. E., Executive Secretary, Federal Power Commission, dated April 7, 1926, in which they recommended that surveys be made for the comprehensive development of 183 specified rivers of the United States together with some of their tributaries. It would be out of place to recall the sequence of events which grew out of these recommendations, except to state that, directly in line with these recommendations, Congress, in the River and Harbor Act of January 21, 1927, authorized examinations and surveys of type similar to that made by Major Fiske on the Tennessee River to be made of all the rivers specified at expenditures estimated to total $7,322,400. These surveys marked the beginning of the most ambitious program of river development that has been witnessed in the annals of engineering in the United States—a program which has made available millions of hydroelectric horsepower and caused thousands of miles of navigable river channels to be improved, in addition to providing extensive flood protection benefits through the construction of high dams for flood-water storage. For the completion of the Tennessee River survey, additional funds were made available, followed by an act of Congress approved on May 18, 1933, which created a special corporate federal agency known as the Tennessee Valley Authority, charged with undertaking actual development work primarily for the promotion of navigation and the control of floods and clothed with authority to develop and sell power. The project as a whole was to be operated by the federal government for the benefit of the people. Colonel Fiske lived to see the day when a major part of his cherished plan, as modified by this act, had become a reality.

Colonel Fiske was elected a Member of the American Society of Civil Engineers on August 4, 1924.

CHARLES BROE GALVIN, M. Am. Soc. C. E.[1]

DIED NOVEMBER 18, 1943

Charles Broe Galvin was born at Jersey City, N. J., on March 9, 1873, the son of Charles Dowling and Ester (Broe) Galvin. He received his education from the International Correspondence School in Scranton, Pa.

In 1890 Mr. Galvin began his career as an apprentice and assistant in the machine shops and engine and dynamo rooms of the Pennsylvania Steel Works at Steelton, Pa. From 1894 to 1896, he was assistant in the street railway electric power plant of the Union Railroad Company in New York, N. Y. In 1896 he served as machinist for the De La Verne Machine Company of New York. From 1897 to 1904, he was employed by the Knickerbocker Athletic Club in New York as a licensed steam engineer.

Because of his health, Mr. Galvin decided to work outdoors and, from 1904 to 1906 he was, respectively, axman, chainman, rodman, and instrumentman for the Highway Engineer Corps of the Borough of the Bronx in New York City. In 1906 he entered the employ of the New York City Board of Water Supply as rodman acting as instrumentman. He then was promoted, successively, to leveler acting as instrumentman; engineer in charge of field party; transitman and computer in charge of field party on preliminary surveys and construction, Hudson River siphon; and finally to assistant engineer.

Leaving the practice of engineering temporarily during 1910 and 1911, Mr. Galvin worked on an invention for surveying deep diamond drill holes, which he later patented. From 1911 to 1913 he traveled extensively in Europe, Asia, and Africa, studying important engineering works; and, from 1913 to 1920, he managed and directed the financial affairs of an estate.

In 1920 Mr. Galvin returned to engineering as draftsman for the New York City Department of Docks (later the Department of Marine and Aviation). He was promoted in 1927 to assistant engineer in charge of drafting, contracts, specifications, and plans for miscellaneous pier and bulkhead structures—a reinforced concrete pier, a three-story hospital superstructure, and floating property and yards. He retired on July 30, 1941.

On October 18, 1910, Mr. Galvin was married at Cornwall-on-Hudson, N. Y., to Antoinette Elizabeth Gazzam. Surviving are three sons, Rodrigo Sheil, Ralph Broe, and Ormond Reading, all in the armed services of the United States. Mrs. Galvin died in September, 1940.

Mr. Galvin was notably of a quiet and serene disposition, and was never known to speak ill of any one. From his father, a journalist, he inherited an acutely analytical mind. In addition to his engineering knowledge, he was widely read in history and astronomy. His interpretation of current events and personages, weighed and appraised in the light of long years of experience, was interesting and instructive. He was musical and was especially fond of early twentieth century classics. His rendition of the old favorites on the violin was as pure and correct as it was modest and unassuming. During the years he traveled extensively in Europe and the Near East, he wrote delightful letters on surveying methods in Cairo, the aqueducts of Rome and Nîmes, the sewers of Paris, and the docks of Liverpool.

---

[1] Memoir prepared by J. P. Hurley and W. H. Yates, Members, Am. Soc. C. E.

Of steadfast and reliable character, at an early age, Mr. Galvin was able to take care of himself under any circumstances. He leaves behind him a host of friends who feel that life has been the better because they knew him.

Mr. Galvin was a member of the National Society of Professional Engineers; Municipal Engineers, City of New York; and Society of American Military Engineers.

Mr. Galvin was elected an Associate Member of the American Society of Civil Engineers on March 15, 1926, and a Member on October 14, 1935.

JAMES MADISON GARRETT, M. Am. Soc. C. E.[1]

Died December 20, 1943

James Madison Garrett was born at Mount Willing, Lowndes County, Ala., on September 24, 1864, the eldest of eight children born to James Madison and Belle (Mooney) Garrett. His ancestors were among the early settlers of the State of Alabama.

After attending schools in Lowndes County, in 1878 Mr. Garrett entered Strata Academy, which became Highland Home College (Highland Home, Ala.) in 1880. After his graduation in 1882, he served for four years as an instructor in English, Latin, and Mathematics at Highland Home College, resigning in 1886 to enter the employ of the Atlantic Coast Line Railroad Company as transitman.

During the succeeding four years Mr. Garrett was engaged in railroad location and construction work for several railway systems which were expanding rapidly in Alabama at that time. His assignments included those of chief of party on location and resident engineer on construction. During this period he made a survey for a complete street railway system in Montgomery, Ala. In 1890 Mr. Garrett left the field of railroad location and construction to become chief engineer for the Standard Coal Company, of Brookwood, Ala. In this capacity, he resurveyed two old mines, supervised the construction of some two hundred coke ovens, and handled other engineering duties.

In the latter part of 1890, Mr. Garrett returned to railroad work, as division engineer for the Louisville and Nashville Railroad Company (Sylacauga-Anniston, Alabama Division) from August, 1890, until January, 1891. In January, 1891, he became resident engineer for the Montgomery-Northwestern Railway Company. In July, 1891, he was appointed county engineer of Montgomery County, Alabama. For the succeeding twelve years, in this capacity,

---

[1] Memoir prepared by a Committee of the Alabama Section consisting of S. W. Harbin, Assoc. M. Am. Soc. C. E., Chairman, J. L. Land, M. Am. Soc. C. E., and A. Reese Harvey, Jr., Assoc. M. Am. Soc. C. E.

Mr. Garrett built a splendid system of county roads and pioneered in the use of local materials for surfacing. During this same period he was county surveyor for Montgomery County, and conducted a general engineering practice in Alabama, Florida, and Georgia. Resigning as county engineer in 1903, Mr. Garrett became chief engineer of the Birmingham, Columbus and St. Andrews Railroad Company, and during the next three years supervised the location survey work on two hundred miles of line and the construction of forty miles of railroad.

In 1906, Mr. Garrett entered the employ of the City of Mobile, Ala., and made a complete city survey in 1907. During this period he also served as county engineer for Mobile County, Alabama. Railway location again appealed to Mr. Garrett, and so in 1908 he became chief engineer on the location of a projected railway from Andalusia, Ala., to Pensacola, Fla.—a distance of about ninety-five miles.

Much work done by Mr. Garrett up to this time had been on a contract basis. Beginning in 1908 and continuing through 1917, he conducted a general engineering practice, principally in Alabama. He was especially interested in highways, street systems, and railroads. In 1918 he organized the engineering firm of Garrett and Slack, specializing in the preparation of surveys and plans on a contract basis for state highway and bridge construction in Alabama and Georgia. During the period from 1916 to 1920 some forty-two state projects covering several hundred miles of roads were located and designed under the supervision of Mr. Garrett. Later the firm of Garrett and Slack did considerable work for various counties and municipalities.

Mr. Garrett was appointed city engineer of Montgomery in 1924, which position he held continuously until 1941. While he was city engineer, he developed a splendid system of paved streets and other municipal improvements, including substantial additions to the water supply and distribution system. A fine municipal airport was designed and constructed under his supervision.

From 1941 until his death, Mr. Garrett was a consulting engineer in partnership with his son, Roy S. Garrett, M. Am. Soc. C. E., in general engineering practice in Montgomery and its vicinity. During the last year of his life his advanced age and failing health kept him from active practice.

Mr. Garrett was a man of splendid character and of fine personality. He was straightforward in his actions. In his profession he employed a code of ethics which created the greatest respect for his decisions. His judgment was respected by all engineers.

He was married in 1889 to Lucy Tankersley of Hope Hull, Montgomery County, Ala., who died in 1910. In 1911 he was married to Mary Barnes, the eldest daughter of his former teacher, J. M. Barnes, one of the founders of Highland Home College. She died in 1930. Three sons by his first marriage—James M., Colonel in the U. S. Army, Roy S., and George T., Captain in the U. S. Army—and one son by his second marriage—Frank B., Major in the U. S. Army—survive him.

Mr. Garrett was a member of the Kiwanis Club, the Society of American Military Engineers, the American Association of Engineers, and a charter member of the Engineer's Club of Montgomery.

Mr. Garrett was elected a Member of the American Society of Civil Engineers on April 17, 1917. He became a Life Member in January, 1942.

WILLIAM GERIG, M. Am. Soc. C. E.[1]

Died April 3, 1944

William Gerig was born on March 25, 1866, at Ashland, Mo., the son of Joseph and Caroline (Degen) Gerig. He was the eldest of six children, four boys and two girls. Five of the children were graduated from the University of Missouri at Columbia, and four were winners of Phi Beta Kappa keys. William Gerig was graduated in 1885 and received the degree of Civil Engineer in 1886. Fifty-two years later the University of Missouri honored their distinguished graduate by conferring on him the degree of Doctor of Laws.

While stationed in Arkansas as a young engineer, working on railroad construction, he met and, in 1890, was married to Frances Crow of Arkadelphia, Ark., who survives him. In 1940 they celebrated their golden wedding anniversary in the same home in which they were married. He is also survived by two children, Frank and Mildred (Mrs. J. L. Newberry).

Beginning his career as a rodman on railroad construction in Arkansas, Mr. Gerig progressed through three years of railroad work, fifteen years with the Mississippi River Commission, three years as division engineer on the Panama Canal, six years as chief engineer and general manager of the Pacific and Eastern Railway in Oregon, six years as consulting engineer and assistant chief engineer of the Alaskan Railroad, and fifteen years as consulting engineer in the Office of the Chief of Engineers, U. S. Army, retiring with the title of head engineer.

In 1889 Mr. Gerig was employed by the Mississippi River Commission, performing such distinguished service that his work was recognized as outstanding. He became an authority on hydraulics, revetments, and dredging. He designed a number of dredging plants and dams, and was given credit for the use of many new theories of hydraulics in dredging. He assisted in the development of Fascine River mats for flood control. He remained with the Mississippi River Commission until 1905. During this period he served also as assistant engineer for the Chicago Drainage Canal. His varied experiences with the River Commission and his successful designs made possible his future eminence as an authority on lock and dam construction, earthworks, dredging, and waterways, and also led, in 1905, to his appointment as division engineer on the Panama Canal.

---

[1] Memoir prepared by a Committee of the Mid-South Section consisting of J. M. Page, Brig. Gen. Max C. Tyler, and Harry N. Pharr, Members, Am. Soc. C. E.

With his family, Mr. Gerig lived in Panama for three years, and contributed much to the construction of that celebrated waterway. His particular problem was "to keep the Pacific out." It is a matter of interest that three dams had been recommended on the Pacific side, but, when the chief engineer, the late John F. Stevens, Past-President and Hon. M. Am. Soc. C. E., asked for Mr. Gerig's opinion, Mr. Gerig advised two dams instead of three. This recommendation was accepted, thus saving the government millions of dollars and rescuing much needed land space for terminal facilities. Mr. Gerig was later transferred to the Atlantic side of the Panama Canal where he was division engineer on the Gatun Locks and Dam. Mr. Gerig served under the three chief engineers in charge of the huge project—Mr. Stevens, John F. Wallace,[2] Past-President, Am. Soc. C. E., and George W. Goethals,[3] M. Am. Soc. C. E. He formed lifelong friendships on this project.

In 1909 Mr. Gerig left Panama to return to railroad construction as vice-president, directing chief engineer, and general manager of the Pacific and Eastern Railway with headquarters in Portland, Ore. During this time he also was consulting engineer for the Spokane, Portland and Seattle Railway Company, and in 1916 consulting engineer for the St. Paul Union Depot Company.

Ever sought as a builder, when but for his modesty and love of his chosen profession he might have become an executive, in 1917 he began, as assistant to the chief engineer, construction of the railroad in Alaska for the federal government. His experiences in Alaska gleaned from letters and newspaper clippings read like a saga. He was not only the master builder, but the master planner—the one person who envisaged the development of transportation as the means of evolving a great new world in the north country. The Anchorage *Daily Times* gives William Gerig the credit for the Anchorage Ocean Dock: "* * * to him alone is due the distinction of working out in all the multiplicity of detail, the finished work, the completed structure, the new dock at Anchorage." This port connected the interior of Alaska—the coal mines, the fisheries, the agricultural industries—with the outside world.

So well, so quietly, and with such a zealous devotion to duty and to his profession did Mr. Gerig work that, in 1923, he was called to Washington as head consulting engineer in the Office of the Chief of Engineers, U. S. Army. He remained with that office until he was retired in 1938.

As consultant on dredging and river and harbor work, Mr. Gerig was a member of the board that assisted in preparing the Jadwin Flood Control Plan, adopted by Congress in 1928, for the Mississippi River. He was consulting engineer on the Florida Ship Canal. (Previously he had been an expert consultant on the New York Barge Canal in 1916, Lake Okeechobee, and various other excavation projects.) As an authority on dams and earthworks, his was the authoritative word on Fort Peck Dam in Montana, Wappapello Dam in Missouri, Sardis Dam in Mississippi, Conchos Dam in New Mexico, Denison Dam in Texas, and work in the Oklahoma-Denver Division.

An unusual distinction was given him in that his retirement age limit was twice extended by Presidential Executive Order, "because the public interest so requires." Even after his retirement, Mr. Gerig remained for several years as consulting engineer on a number of projects, such as the Lake Okeechobee Flood Control Project and the Fort Peck Dam (a $100,000,000 project), and was frequently called to the board meetings concerning them.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXV (1922), p. 1635.

[3] For memoir, *ibid.*, Vol. 93 (1929), p. 1813.

He contributed many articles to professional magazines, such as the *Military Engineer* and *Dredge Design and Operation.*

William Gerig was one of America's most eminent engineers. He was a master builder, a man of vision with the courage and force to carry out his convictions. His devotion to duty was his most remarkable characteristic; his devotion to his profession was inherited. It has been stated, "* * * if there is a continent to cut in two there will be a Gerig there." Mr. Gerig's father was an engineer on the Suez Canal, Mr. Gerig was at Panama, Frank Gerig is an engineer in Arkansas, and Capt. Frank Gerig, Jr., who was graduated from the U. S. Military Academy in West Point, N. Y., in 1941, is in the service of the U. S. Engineer Corps.

The fact that William Gerig was congenial with his fellow workers is well illustrated by his years of service with government officials. He served under four Chiefs of Engineers, U. S. Army. To the men who worked with him, sometimes high ranking in Army and Navy, his word was the final authority. Many testimonials of his careful concern and influence in their behalf have come to his family.

In Arkadelphia where he chose to make his home, he was loved for his friendliness and sincerity. His quiet dignity concealed the fact that he had achieved eminence. His modest retiring but courtly bearing covered the greatness of his accomplishments and made him revered as a friend—a citizen of a small town. It is fitting that we quote from the *Arkadelphia Standard:*

> "William Gerig left a great deal more than useful monuments of his engineering skill in this world as he went along. * * * His quiet dignity and respectability, his belief in the integrity of men, brought out these qualities in others and gave encouragement and inspiration to those with whom he progressed along the pathway of life.
>
> "Such a man creates no grief in the world but gives off happiness and reassurance. In the warm glow of such virtues we find it hard to mourn, even though we do miss his lovable personality."

He belonged to the Society of American Military Engineers, the Masonic Order, and the Presbyterian Church. He was a member of Tau Beta Pi (national honorary engineering fraternity), Phi Beta Kappa, and held the degree of Doctor of Laws from the University of Missouri.

Mr. Gerig was elected a Member of the American Society of Civil Engineers on March 5, 1902. He became a Life Member in 1937.

HERBERT THURSTON GERRISH, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 6, 1943

The statement that Herbert Thurston Gerrish spent most of his active life near the sea would certainly not be an exaggeration. Mr. Gerrish loved the ocean, whether he was sailing boats with his children off Falmouth on Cape Cod, Massachusetts, or supervising dredging projects in the waters of the Atlantic. However, Mr. Gerrish's major love was his profession. He was a very hard worker and his only real extended vacation from his home in Melrose, Mass., was his honeymoon.

Herbert Thurston Gerrish, the son of John and Ida (Thurston) Gerrish was born in Portland, Me., on July 6, 1886. After being graduated from Massachusetts Institute of Technology in Boston in 1908, he immediately became connected in business with his father who was the president of the Eastern Dredging Company. At this period the Eastern Dredging Company was the largest dredging organization in the northeastern United States, owning, approximately, 34 dredges, 60 to 70 towboats, and more than 200 dump scows.

Mr. Gerrish surpervised the dredging of rivers and harbors in New England, New York, and New Jersey. In Massachusetts he directed work on Cape Cod, the Charles River Dam, West Boston Bridge, Charles River conduits, and filling for the Boston Fish Pier. At this time, Mr. Gerrish became quite interested in Florida, then being developed into a major resort. In fact, the Eastern Dredging Company was one of the first companies to operate a dredge at Miami, Fla. During this period Mr. Gerrish supervised dredging of Matanzas Inlet from St. Augustine, Fla., to Lake Okeechobee, Florida, and dredging at Miami and Miami Beach. From 1916 to 1919 Mr. Gerrish was with the Army engineers. At the close of World War I, he was Captain, commanding Company F, 218th Engineers, Camp Travis, Texas.

In 1917, after his release from the United States Army, he became treasurer and general manager of the Gerrish Dredging Company and the Trimount Dredging Company. In this capacity, he directed such projects as large playground improvements at Rye, N. Y., dredging and filling on Cape Cod, and dredging in the rivers and harbors of New England, New York, and New Jersey.

As an alumnus of Massachusetts Institute of Technology, he was very much interested in working with professors on problems of soil erosion and soil mechanics. Mr. Gerrish was a Past Master of Wyoming Lodge (Masonic Order) and a member of Waverly Royal Arch Chapter, Hugh de Payons Commandery, and The Aleppo Temple. He belonged to the Boston Society of Civil Engineers and the Boston Engineers Club.

At Somerville, Mass., in September, 1913, Mr. Gerrish was married to Edna Whitney. He is survived by his widow; a daughter, Nancy; a son, Whitney,

---

[1] Memoir prepared by William H. Ellis, Affiliate Am. Soc. C. E.

Master Sergeant in the U. S. Army; five sisters, Louise Gilbert, Alice Hanson, Lelia Phillips, Alma Hight, and Ruth M. Gerrish; and two brothers, Maurice S. and John Jordan.

Mr. Gerrish was elected an Associate Member of the American Society of Civil Engineers on October 14, 1919, and a Member on July 16, 1928.

LESLIE WARREN GODDARD, M. Am. Soc. C. E.[1]

Died April 6, 1944

Leslie Warren Goddard was born on October 30, 1860, at Lena, Ill., the son of Warren Caleb Goddard and Perly (Skeel) Goddard.

He was educated in rural schools and taught in rural schools prior to entering high school in Ann Arbor, Mich., where he prepared for the University of Michigan, also in Ann Arbor. He was graduated in the class of 1886, with the degree of Bachelor of Science in Civil Engineering.

From July, 1886, to June, 1890, Mr. Goddard worked on railroads and on city surveying in Chicago, Ill., and in Los Angeles, Calif. In June, 1890, he came to Grand Rapids, Mich., as assistant engineer in the U. S. Engineer Department, and continued to work on the harbors of Lake Michigan, ultimately having local charge of the Grand Rapids office under officers of the Corps of Engineers, U. S. Army. The district included all rivers and harbors along the east shore of Lake Michigan. He retired from active duty after forty years of service in November, 1930, continuing to reside in Grand Rapids and wintering in Saint Petersburg, Fla.

Mr. Goddard's work concerned design, construction, and maintenance of harbor structures and navigable channels. In 1905 he was in charge of the improvement of the Grand River from Grand Rapids to Grand Haven, Mich. In this connection, he wrote occasional articles on the effects of storms.[2] A trip to the Panama Canal in 1914 furnished him with pictures and engineering data for lectures on that interesting project. He served as a member of the International Congress of Navigation and was greatly interested in the economics of navigation on the Great Lakes. However, because of political aspects, he never felt free to publish his views on controversial matters. As an employee of the U. S. Engineer Corps, he fulfilled his duty by making the best possible public use of the funds granted by Congress; responsibility for prescribing the expenditures rested on the elected officials.

In spite of his exceeding modesty, his exemplary character was admired by all who knew him; and many a young engineer was inspired by his life and counsel. Mr. Goddard was especially interested in work for boys and young men, and gave freely of his time in teaching at church and the Young Men's Christian Association. He had been a member of the official board of the

---

[1] Memoir prepared by Robert H. Merrill, M. Am. Soc. C. E.

[2] *Engineering News*, 1908, I, p. 594; 1912, II, pp. 91 and 171.

First Methodist Church since 1894 and became secretary of the board of trustees in 1914. For more than forty years he served the church school. In 1934 he was appointed a member of the board of trustees of the Clark Memorial Home in Grand Rapids. He was church historian since the building of a new edifice in 1936.

Mr. Goddard was a member of York Lodge, F. and A. M.; the Sons of the American Revolution; and Round Table International. He was a life member of the Western Society of Engineers, and a charter member of the Grand Rapids Engineers' Club. He was a loyal supporter of the University of Michigan alumni association.

On September 26, 1914, Mr. Goddard was married to Mina Bodine of Saline, Mich., who died in 1932. On August 23, 1938, he was married to Mrs. Nellie McNaughton Kendrick of Flint, Mich., who survives him.

Mr. Goddard was elected an Associate Member of the American Society of Civil Engineers on March 2, 1892, and a Member on October 6, 1908.

PAUL HANSEN, M. Am. Soc. C. E.[1]

DIED FEBRUARY 6, 1944

Paul Hansen was born at Arlington, Va., on August 9, 1879, the only son of John and Pauline (Meyenberg) Hansen. His father was a prominent jeweler in Washington, D. C.

Mr. Hansen received his early education in the public schools of Washington, D. C. Greatly interested in the High School Cadet Corps, he became a captain in his senior year. In 1903 he was graduated from the Massachusetts Institute of Technology at Boston, with the degree of Bachelor of Science in Sanitary Engineering.

While an undergraduate, he worked, in the summer of 1901, with a survey party of the U. S. Geological Survey, and, in the summer of 1902, with the engineering department of the Massachusetts State Board of Health.

After graduation, from June, 1902, to May, 1904, Mr. Hansen served in the engineering department of the Massachusetts State Board of Health. He then joined the staff of the late John H. Gregory,[2] M. Am. Soc. C. E., as an assistant engineer on the Improved Water and Sewerage Works at Columbus, Ohio. From January to October, 1905, he was chief engineer of the Pittsburgh Filter Manufacturing Company in Pittsburgh, Pa., installing water purification plants. From 1906 to 1910, he served as first assistant and later as chief engineer of the Ohio State Board of Health. From August, 1910, to October, 1911, he was state sanitary engineer of Kentucky. In 1911 Mr. Hansen became the engineer of the Illinois State Water Survey, and lectured at the University of Illinois in Urbana on Sanitary Engineering. In 1915 he was appointed chief engineer of the Illinois State Board of Health, remaining in this position until 1917, when he volunteered for service in the U. S. Army. His knowledge of military science and sanitary engineering attracted attention. He served for twenty-one months during World War I (1917–1919) as Captain with the American Expeditionary Force in France on the staff of Gen. John J. Pershing, specializing in water supply problems.

---

[1] Memoir prepared by W. W. De Berard, Samuel A. Greeley, and Langdon Pearse, Members, Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 102 (1937), p. 1552.

After the Armistice, Mr. Hansen returned to the Illinois State Board of Health. Desiring to enter private practice, in May, 1920, he joined in forming the firm of Pearse, Greeley and Hansen with headquarters in Chicago, Ill. Later, in 1931, upon the retirement of Mr. Pearse, the firm became Greeley and Hansen. The firm specialized in water supply, water purification, sewerage and sewage, and refuse disposal. Mr. Hansen was keenly interested in water works. Among the water works projects with which he was particularly identified were the earth dams at Bloomington, Ind., and Litchfield, Ill.; and water supply works at Centralia, Evanston, Highland Park, Kenilworth, Lake Forest, Moline, Wilmette, and Winnetka, Ill.; Benton Harbor, Mich.; Danville and Harrodsburg, Ky.; East Chicago and Hammond, Ind.; Eau Claire and Portage, Wis.; and Sandusky and Toledo, Ohio.

At the time of his death Mr. Hansen was engaged, for the firm, as consultant on the South District filtration works for the City of Chicago and for the Washington (D. C.) Aqueduct Commission on additions to the water supply works of the District of Columbia. In the water works field, he served as an expert witness in various rate cases, including that of the Indianapolis (Ind.) Water Company, usually on behalf of the municipality or state. In the sewerage field, he was active on projects for Buffalo, N. Y.; Peoria, Ill.; Philadelphia (Pa.) Authority; Hampton Roads (Va.) Sewerage Commission; Austin, Minn.; Eau Claire and Portage, Wis.; Hinsdale, Ill.; Evansville, Ind.; Sioux Falls, S. Dak.; and many other municipalities.

During World War II he was actively engaged in advising the War Department on various projects, as well as in planning and constructing water and sewerage facilities for Camp Forrest, Tenn., and for several ordnance works.

Among the earlier achievements of his career, Mr. Hansen esteemed highly the organization of the public health engineering work for the state boards of health in Kentucky and Illinois. In the forty years of his professional life he accomplished his ambition—becoming one of the prominent sanitary engineers in the United States. He was a skilful and resourceful engineer, and withal a student of human relations. Traveling widely in his professional work, he possessed a large circle of friends. Although a busy man, he found time to serve on various committees of the Society and of the American Water Works Association. He also prepared a number of papers on topics mostly concerned with water purification or public health. His kindly humor enlivened many a meeting. He was active in the technical societies. His works will live after him as a worthy monument. Those who knew him well mourn the loss of a firm friend.

He enjoyed occasional relaxation in an auto or fishing trip. Although he had no special hobbies, he liked fine china, and good music, plays, and reading.

Paul Hansen belonged to the Western Society of Engineers, American Public Works Association, American Association of Engineers, American Water Works Association, New England Water Works Association, Central States Sewage Works Association, Society of American Military Engineers, and Sigma Xi fraternity. He was a fellow of the American Public Health Association. In addition to his technical activities, he was a member of the University Club of Chicago, Rotary Club of Chicago, Executives Club of Chicago, American Legion, and Theta Xi.

On October 8, 1905, he was married to Alison May Scott. He is survived by his widow; two children, Elizabeth Scott (Mrs. Henry Pope, Jr.) and Dr. Paul Scott Hansen; and five grandchildren, Alison Scott Pope, Nancy Pope, Katherine Pope, Judith Coit Hansen, and Celia Coit Hansen.

On February 6, 1944, after a short illness, Mr. Hansen died of a coronary thrombosis at his residence in Chicago. For a number of years he had suffered from high blood pressure and overweight, and had been warned to be careful, but the responsibilities and worries of war time caught him unprepared.

Mr. Hansen was elected a Junior of the American Society of Civil Engineers on January 3, 1905; an Associate Member on April 1, 1908; and a Member on December 3, 1913.

CLINTON LEE HARRIS, M. Am. Soc. C. E.[1]

DIED NOVEMBER 15, 1944

Clinton Lee Harris, the son of Thomas Reyford Harris and Margaret (Lee) Harris, was born on January 28, 1886, at Fair Play, S. C.

His paternal ancestors came to the United States from Wales. The earliest ancestor that has been identified in America was the Rev. John Harris—a minister, educator, and Revolutionary War soldier, who came from the eastern shore of Maryland and who by 1778 resided in Boonesborough, Long Cane Section, South Carolina. Mr. Harris' earliest maternal ancestor in America was the Rev. David Humphreys, a minister who, with other refugees, came from England to Philadelphia, Pa., in 1682, seeking religious freedom.

After attending the public schools at Fair Play, Mr. Harris entered The Citadel, a military college in Charleston, S. C., receiving the degree of Bachelor of Science in Civil Engineering in 1909. He received the degree of Civil Engineer in 1916 from The Pennsylvania State College at State College. Immediately after graduation from The Citadel, Professor Harris served for two years as principal and teacher of mathematics in the high school at Latta, S. C. During the academic year of 1911–1912, he was the commandant of cadets at the Nebraska Military Academy in Lincoln, Nebr. During the academic year of 1912–1913, he served as professor of mathematics at the University School in Montgomery, Ala.

---

[1] Memoir prepared by R. M. Gerhardt, Asst. Dean, School of Eng., The Pennsylvania State College, State College, Pa.

In 1913 Professor Harris joined the faculty of the School of Engineering of The Pennsylvania State College, as an instructor in drawing and descriptive geometry. He became an instructor in architectural engineering in 1916, assistant professor in 1917, associate professor in 1919, and professor of architectural engineering in 1926. He was professor of architectural engineering until his death.

During the summers, Professor Harris practiced engineering. In 1917 he was with the Bethlehem Steel Corporation Plant at Steelton, Pa., designing and detailing falsework for the steel railroad bridge across the Ohio River at Louisville, Ky. In 1918 he was engaged by The Austin Company of Cleveland, Ohio, on the erection of factory buildings at Columbus, Ohio, and on the erection of the roundhouse at Nelsonville, Ohio. In 1919 he worked on the design, detailing, and erection of two engineering buildings at The Pennsylvania State College.

As a registered professional engineer and architect in Pennsylvania, Professor Harris had an active practice. In State College, he worked on the structural design and erection of the addition to the State College High School, the erection of the addition to the Methodist Episcopal Church, construction of the Baptist Church, the erection of the Episcopal Church, and the building of the Faith Reformed Church. Professor Harris also acted as engineer for The Pennsylvania State College on such projects as the installation of the Imhoff tank and of sludge and drying beds; the preliminary studies for the Recreational Building; and the steel design of the Horticultural Building. The last professional work upon which Professor Harris was engaged was the design of a large concrete tank for use in the manufacture of shells for a war plant at Williamsport, Pa.

On sabbatical leave from the college in 1932 and 1933, Professor Harris was a member of the Research Association of the National Bureau of Standards, at Washington, D. C. The results of his research during these years were published in "Influence of Neighboring Structures on the Wind Pressure on Tall Buildings"[2] and in technical periodicals both in the United States and abroad. He conducted such research projects at The Pennsylvania State College as "Determination of the Stress of Cables Under Varying Conditions of Loading" and "The Structural Design and Support of Camouflage Nets." Professor Harris was also an associate author of "Building or Buying a House,"[3] which he completed shortly before his death.

A recognized leader in community affairs at State College, Professor Harris served as vice-president of the board of trustees and chairman of the building committee of St. Paul's Methodist Church, as president of the Wesley Foundation, and as a director of the First National Bank. He was a member of the borough council of State College from 1927 to 1930 and president during 1930. He was a member of the following professional and honorary organizations, in addition to the Society: American Association for the Advancement of Science, Society for the Promotion of Engineering Education, American Association of University Professors, Sigma Xi, Sigma Tau, Scarab, and Pi Gamma Alpha. He was a Mason, and belonged to the college "X-Club" and the Centre Hills Country Club.

---

[2] "Influence of Neighboring Structures on the Wind Pressure on Tall Buildings," by Clinton Lee Harris, *Bulletin No. 43*, The Pennsylvania State College, State College, 1934.

[3] "Building or Buying a House," by Johnstone and Associates, Whittlesey House of McGraw-Hill Pub. Co., Inc., New York, N. Y.

Professor Harris was a modest, conscientious man who was always praiseworthy and well qualified. His unselfishness, sincerity, insight, and astuteness, coupled with the objective viewpoint that he applied to every problem, made his counsel and advice sought and welcomed by men in the many stations of life. In all things he was thorough and untiring, with infinite patience, always giving unsparingly of himself to his students, to his professional duties, and to his many other interests.

For more than thirty years, his life was devoted to the instruction of the many students in engineering who were enriched by his teaching. His remarkable memory, especially for former students, identified him as one of the most unusual of men. Although he never temporized when a question of principle or discipline was involved, Professor Harris was revered and known affectionately among the students as "Poppy" or "Coach." He was their devoted friend, wise in counsel, tolerant in judgment, and beloved by all.

On July 23, 1913, in Due West, S. C., Professor Harris was married to Lula A. McGee. He is survived by his widow and by a son, Rhett Gibbs Harris (Major, Army of the United States).

Professor Harris was elected an Associate Member of the American Society of Civil Engineers on August 28, 1922, and a Member on November 9, 1936.

ELMO GOLIGHTLY HARRIS, M. Am. Soc. C. E.[1]

Died December 21, 1944

Elmo Golightly Harris was born on June 27, 1861, near Spartanburg, S. C. He was the son of David Golightly and Emily (Liles) Harris. His paternal forebears were of early American stock and came to Boston, Mass., from London, England, finally settling in North Carolina during the early 1700's. His father, David Golightly Harris, owned and operated a large cotton plantation with all the necessary buildings and appurtenances, including slaves. Since Mr. Harris was only four years old when the Civil War ended, his boyhood was spent during the most strenuous and trying years of the reconstruction era. These early pioneer conditions profoundly affected his life, fixed his pleasures, decided the field of endeavor in which he later reached eminent success, and molded the outstanding qualities of his sterling character.

His early education was acquired in a one-room log cabin. He went to school when plantation work was slack. He later attended a private school or

---

[1] Memoir prepared by E. W. Carlton and Joe B. Butler, Members, Am. Soc. C. E.

"Academy" and a high school in Spartanburg. After completing high school he entered the University of Virginia at Charlottesville in 1880 to study civil engineering. The course of study was undeveloped and satisfactory textbooks were nonexistent. Teaching was chiefly by lectures—hence, little ground could be covered. After two years of work at the university, he received the degree of Civil Engineer on his twenty-first birthday (June 27, 1882). Among his classmates at the University of Virginia was William H. Echols, a very talented mathematician, who proved a most loyal friend and benefactor during the years to come.

At the time of Mr. Harris' graduation, many railroads were being constructed in the United States, and he played a prominent part in surveying routes for many of these lines in the South and Southwest. He was in charge of surveying for the location of the Missouri Pacific Railroad Company from Van Buren, Ark., to Kansas, planning lines that have been in operation for more than half a century. Mr. Harris was later employed by the Cotton Belt Railroad Company in charge of rebuilding the bridge over the Arkansas River at Rob Roy near Pine Bluff, Ark. This task involved great responsibilities and experiences. New piers had to be built under the old bridge while traffic was maintained. These piers were placed by the pneumatic process; and, in watching and studying the process of blowing out the sand with compressed air, Mr. Harris discovered, independently, the principles involved in the "Air-Lift Pump." Although these principles had been discovered previously, nothing had been published and the theory had not been evolved. Through his study and development of the theory of the air-lift pump, he became interested in compressed air. He later published a textbook on compressed air,[2] which enjoyed wide use in colleges.

In July, 1895, Mr. Harris wrote an article on the "Theory of the Air-Lift Pump."[3] (He had applied for a patent on the air-lift pump which had been twice rejected by the patent office because "it was contrary to the laws of physics and would not work." Nevertheless, a patent was granted a few months later to another man on claims that were absurd and contrary to the laws of physics. Mr. Harris noted all these facts in his article.[3]) As a result, the air-lift pump was freed of patent restrictions. Mr. Harris designed and laid out the first water works and sewerage system for the City of Rolla (Mo.), and the air-lift pump was used on Rolla's deep well water supply installation. Later, he developed a return air pump that was widely used until the development of the electrically driven centrifugal pump. The return air pump is still valuable, however, in pumping gritty material such as sand, gravel, and so forth. An early outstanding installation of this type of pump was on the New York City (N. Y.) water supply.

For several years Mr. Harris practiced civil engineering in Little Rock, Ark. During this time he explored and surveyed much of the great timber area in the St. Francis swamp region, together with some of the earlier highways in Arkansas.

---

[2] "Compressed Air," by Elmo G. Harris, McGraw-Hill Book Co., Inc., New York, N. Y., 1910.

[3] "The Theory of the Air-Lift Pump," by Elmo G. Harris, *The Journal of the Franklin Institute,* July, 1895, p. 32.

Through the influence of his good friend, Mr. Echols, Mr. Harris joined the faculty of the Missouri School of Mines and Metallurgy at Rolla in the fall of 1891 as director and professor of civil engineering. Two years later, he gave up his directorship and devoted all his time to teaching. He specialized in a wide range of subjects—mining, engineering drawing, surveying, hydraulics, highway engineering, concrete, structures, railroad engineering, water supply, sewage, contracts, and specifications. Many of his students have attained world-wide distinction in various fields of engineering. One of the more famous was D. C. Jackling, who revolutionized copper mining methods and whose discoveries have doubled the world's supply of copper.

Professor Harris continued his research and developed many revolutionary ideas which attracted international attention. He published the first treatise on centrifugal pumps (which lift a greater volume of water than all other pumps combined). In connection with the computation of the flow of water in uniform channels, he developed a chart for the Manning formula covering one page of a textbook—replacing some two hundred pages of tables formerly used for the same purpose.

Professor Harris' written contributions to the engineering profession are along numerous lines, and many of them appear as bulletins of the Missouri School of Mines and Metallurgy. His early studies were mainly on compressed air and hydraulics, whereas his later studies were largely on concrete arch dams, retaining walls, and highway bridges. All in all, Professor Harris wrote some thirty-four published technical articles and bulletins and also numerous unpublished studies in the field of structures and economics. Professor Harris first called attention to the possibility of a hydroelectric power plant on the Ouachita River in Arkansas (at the site of the Carpenter Dam which furnishes power for Hot Springs, Little Rock, and elsewhere). He was a strong advocate of good roads and in 1919 wrote a treatise on "Road Problems in the Ozarks" which was widely used during the highway development of southern Missouri.

In the fall of 1931 Professor Harris was appointed professor emeritus of civil engineering, and in 1938 a new building on the campus to house civil engineering was named Harris Hall in his honor.

Throughout his life Professor Harris had a diversity of interests. He especially loved the Ozark hills, woods, and streams. He was a noted hunter and woodsman and an active gardener, cultivating flowers, fruits, and vegetables. He gave much attention to building and maintaining residences. Professor Harris was a Southern gentleman in its truest and highest sense, a devoted husband and father, a good neighbor, and a loyal supporter of religious and civic activities.

The death of Professor Harris breaks the direct contact of the faculty of the School of Mines with the nineteenth century and the early days of the school. His service to the School of Mines covers fifty-three of the seventy-four years of its existence. More than 98% of the 3,100 alumni were graduated while Professor Harris was with the school.

A few years before he died Professor Harris stated in his memoirs:

> "The Period of 'rugged individuality,' wholesome achievement, peace and security in which I have lived is past. We are at a turning point in human affairs."

Professor Harris' philosophy of life is best expressed in a prayer written by himself and often repeated by his family:

> "God Thou Great Mystery. Thou hast made me I know not why. Pity my ignorance, forgive my weakness. Thou hast given a blessed life. I am grateful and trust Thee to direct me through to some good purpose according to your all wise plan."

On April 24, 1890, Professor Harris was married to Zoe Barrow, who preceded him in death. He is survived by four daughters, Jean (Mrs. George C. Willson), Zoe Harris, Dixie (Mrs. Clarence H. Burrage), and Emily (Mrs. Glenn A. Dooley); seven grandchildren, Mrs. Charles A. Bemis, George C. Willson, III (Ensign, U. S. Navy), Jean Harris Dooley, Zoe Harris Dooley, Jean Burrage, Emily Barrineau Burrage, and Mary Ella Burrage; and one great-grandchild, Victoria Ann Bemis.

Professor Harris was an honorary member of Phi Kappa Phi and Sigma Xi. He also belonged to various Masonic orders and was active in local civic organizations.

Professor Harris was elected a Member of the American Society of Civil Engineers on October 2, 1901. He became a Life Member in January, 1932.

BERTHOLD FRANCIS HASTINGS, M. Am. Soc. C. E.[1]

DIED AUGUST 11, 1944

Berthold Francis Hastings, the son of Joel W. and Esther (Lowenthal) Hastings, was born in Brooklyn, N. Y., on October 20, 1888.

After graduation from high school, he entered the Sheffield Scientific School, Yale University, in New Haven, Conn., from which he was graduated with the degree of Bachelor of Philosophy in 1910. He received the degree of Mining Engineer in 1912. During summer vacations while at Yale, he was engaged in general engineering work in various mining camps in different sections of the United States.

After graduation, during 1912 and 1913, he worked on erection and design, gaining both field and office experience, for the United States Reclamation Service on the Elephant Butte Dam in New Mexico. Immediately following this engagement, he became instructor in various civil engineering subjects, including the theory of reinforced concrete, at the University of Pennsylvania, in Philadelphia. From 1914 until 1916, he taught mathematics at the Bridgeport (Conn.) High School, and conducted a private practice in general engineering. He then became structural draftsman on hydroelectric and transmission line design for the New England Power Company, at Worcester, Mass.

---

[1] Memoir prepared by F. H. Frankland, M. Am. Soc. C. E.

During 1917 Mr. Hastings was designer and estimator for the Porcupine Steel Company of Bridgeport. In this capacity, he worked on the design of various types of steel structures, the most important of which was the Bullard Gun Plant for the manufacture of ordnance. Following this engagement, he became assistant to J. E. Kirkham, M. Am. Soc. C. E., professor of structural engineering at Iowa State College in Ames, on consulting work for the Iowa State Highway Commission, and at the same time was given charge of instructing upper classmen and graduate students in the design of steel and reinforced concrete. At the end of the school year he undertook a special assignment in the bridge department of the New York, New Haven and Hartford Railroad Company at New Haven, analyzing the capacity of existing bridges on the railroad and directing the design work involved in the necessary strengthening for increased load capacity. This work required a high degree of judgment and design skill.

From the early part of 1919 to the latter part of 1921, Mr. Hastings served as designing structural engineer for the late H. G. Balcom, M. Am. Soc. C. E., of New York, N. Y. While with the Balcom organization, Mr. Hastings had complete charge of the structural design of many important buildings, such as the Ritz-Carlton Hotel and the Ambassador Hotel, both at Atlantic City, N. J. The Ambassador Hotel was the first large structure in southeastern New Jersey to be built on spread footings, instead of piles. Another important structure for which he had direct charge of the determination of stresses, deflections, design of members, and details was the Sixteenth Street Bridge in Pittsburgh, Pa. Following the completion of the design for the Sixteenth Street Bridge, he became representative engineer for Warren and Wetmore, the architects on the project, and was in general charge of the erection and inspection in the mill, shop, and field.

In the autumn of 1922, Mr. Hastings was appointed associate professor of structural engineering at Carnegie Institute of Technology, in Pittsburgh, serving in that position until June, 1928. While with Carnegie Institute of Technology, he was also engaged in private practice as a consulting structural engineer on such buildings as the William Penn Hotel Annex, a 35-story hotel, and the Keystone Athletic Club, a 27-story residential club—both in Pittsburgh.

From June, 1928, until his death, Mr. Hastings served as district engineer for the American Institute of Steel Construction, with headquarters in Philadelphia. His work during this period consisted mainly of engineering and economic consultations with architects, engineers, and financial interests, relating to the proper and economic use of structural steel in buildings and bridges.

Mr. Hastings' training, experience, and inclination led him to intensive studies on the economics of structural design. He was keenly interested in the effect of sociological changes on political trends. He was active in local and national engineering organizations, and was President of the Philadelphia Section of the Society in 1937. As chairman of Committee A-57 on Building

Code Regulations for Steel and Iron of the American Standards Association, he steered the development of these regulations with great success until they became an American standard in 1943. While he was with the American Institute of Steel Construction, he was frequently called upon by various municipalities for advice on building code work and on various bridge design problems. He was a registered professional engineer in New York and Pennsylvania.

Mr. Hastings was qualified, as few are, as a teacher and was remarkably successful in this field. His integrity never permitted him to deviate from the search for truth in the many engineering investigations with which he was connected. This quality and that of loyalty to his friends endeared him to all those who were privileged to know him well.

In 1913 Mr. Hastings was married to Loretta M. Buckley of Bridgeport, who died in 1940. He is survived by a son, Frank Hastings (Sergeant, U. S. Army Air Forces), and a daughter, Virginia Hastings. Another daughter, Joan Margaret, died in 1939.

Mr. Hastings was elected an Associate Member of the American Society of Civil Engineers on July 6, 1920, and a Member on December 4, 1922.

EMILE HENRY HEILBRON, M. Am. Soc. C. E.[1]

DIED FEBRUARY 10, 1945

Emile Henry Heilbron was born at Rochester, N. Y., on November 14, 1872. He was the son of Christian and Mary (Snyder) Heilbron. He was reared at Sea Breeze, near Rochester, and was educated in the public schools of Rochester.

In 1891 Mr. Heilbron moved to Chicago, Ill.; and, in 1892, he entered the service of The Sanitary District of Chicago. He remained in the employ of The Sanitary District of Chicago until his death—a period of fifty-two years. Beginning as a flagman on preliminary surveys for the Summit and Willow Springs divisions of the Chicago Drainage Canal, he gradually rose through the grades of computer, subinstrumentman, and subassistant engineer on canal construction, to assistant engineer in 1902. From 1902 to 1905 he directed topographic surveys in the Illinois River Valley and acted as a hydrographer for the U. S. Geological Survey, on discharge measurements of the Des Plaines, Illinois, Fox, and Sangamon rivers in Illinois.

From 1906 to 1913, as division engineer, he made a detailed topographic survey of the Illinois River Valley and compiled data relative to overflow lands, involving damage suits totaling some $12,000,000 against The Sanitary District of Chicago resulting from the diversion of water from Lake Michigan through the Chicago Drainage Canal into the Illinois River. From 1913 until his death, Mr. Heilbron was Illinois Valley engineer for the sanitary district, reporting to the attorney of the district. During this period, surveys were made and data were compiled for the Illinois River and its bottom lands. Topographic surveys and maps of more than 200,000 acres were completed, as were resurveys to determine crop areas on nearly 600,000 acres. Location and profiles were obtained for the 390 miles of levees that protect nearly half the bottom lands along the lower 200 miles of the Illinois River. Many reports were prepared relating to overflow lands, flood heights, and damages. In all this work Mr. Heilbron was closely connected with the defense of the sanitary district against overflow claims and suits in the Illinois Valley, and with the settlement of claims. Until 1925 some 237 suits, of the 458 filed, were pending. In 1925 the board of trustees of the Sanitary District created an Illinois Valley Claims Commission. New suits and claims brought the total filed to 1,827. When Mr. Heilbron died, 575 suits and claims, involving alleged damages of about $8,000,000 to nearly 100,000 acres, were still pending. As a result of his years of contact with the problems of the Illinois River Valley, Mr. Heilbron was probably the best informed engineer in Illinois on the status of overflow lands, crops, and reclamation, covering the 285 miles of the Illinois waterway from Joliet to Grafton, Ill., with an overflow area of about 400,000 acres.

---

[1] Memoir prepared by Langdon Pearse, H. P. Ramey, and H. S. Ripley, Members, Am. Soc. C. E.

In 1910–1911 Mr. Heilbron also served as consulting engineer for the Submerged and Shore Lands Legislative Investigating Committee of the Forty-Ninth General Assembly, State of Illinois. This committee presented a comprehensive report covering the entire state. At other times he advised on the reclamation of swamp areas in Illinois, Wisconsin, and Missouri, and testifed as an expert in the case of the United States versus the Economy Light and Power Company, which involved the question of navigability of the Des Plaines River.

At the time of his death he was a life member of the Western Society of Engineers which he joined on March 7, 1900. He also belonged to the Illinois Society of Engineers from 1913 to 1932. He was the third oldest member of the Masonic Blue Lodge at La Grange, Ill. (which he joined in 1895), and also a Knight Templar and a Shriner (Medinah Temple, Chicago, since 1903).

After 1909 Mr. Heilbron resided at Chillicothe, Ill. He was physically strong and a born outdoor man, very fond of athletics, boating, riding, hunting, and fishing. Duck shooting was his favorite recreation. For years he owned and supervised a duck club on the Illinois River. From 1921 to 1931 he also maintained a hunting base in Wyoming. His home was on the bluff above the Illinois River, surrounded by a show yard, including a rock garden, sunken garden, and pools. On February 10, 1945, the automobile which Mr. Heilbron was driving was struck by a train in Chillicothe. He was killed instantly, together with his daughter-in-law, Mrs. Harriet Heilbron, and a youth, Patrick Mooney.

Mr. Heilbron was married three times: In 1895 to Mona Abbitt, in 1907 to Ella Walther, and in 1943 to Mrs. Berdie (Gegenbach) Booker. He is survived by his widow; three daughters, Ruth Heilbron, Marie (Mrs. Howard Hart), and Ella Henrietta Heilbron; two sons, Lee Abbitt Heilbron and

Edward Henry Heilbron (Lieutenant, U. S. Army); and a sister, Cordelia (Mrs. Francis J. Nugent).

Mr. Heilbron was elected a Member of the American Society of Civil Engineers on September 10, 1923.

GEORGE HEWITT, M. Am. Soc. C. E.[1]

Died June 24, 1944

George Hewitt was born in Paterson, N. J., on January 30, 1876, the son of William and Mary (Rainey) Hewitt.

He attended the local grade and high schools and the Rogers and Magee Preparatory School. In 1892 he entered Stevens Institute of Technology at Hoboken, N. J., being graduated in June, 1896, with the degree of Mechanical Engineer.

From 1896 to 1906 Mr. Hewitt was employed by the Passaic Rolling Mill Company, of Paterson, of which George H. Blakeley,[2] M. Am. Soc. C. E., was chief engineer.

On July 1, 1906, he joined the writer in forming the partnership of Lee and Hewitt, Engineers and Architects, with offices in New York, N. Y., and Paterson. The firm did general engineering work, specializing in manufacturing, industrial and power plants, and school buildings.

From January 1, 1934, until December 20, 1938, Mr. Hewitt served as county engineer and road supervisor for Passaic County, New Jersey. During this time he was also a member of the Passaic County Planning Board and the Passaic Valley Flood Control Commission (treasurer).

During World War I, Mr. Hewitt was engineering manager of the Boston (Mass.) Ordnance Office, and, during World War II, he served on the construction of the new naval base at Bayonne, N. J., on the new dry dock at this base, and with the Wright Aeronautical Corporation in the Engineering Department.

Mr. Hewitt was married twice. His first wife was Nellie Latham to whom he was married on April 14, 1903. She died on April 3, 1923. Two children of this marriage, Frances Elizabeth and William Latham, survive him. On November 9, 1925, he was married to Irma Marselus Post, who, with a son, Edward Spear, also survives him.

Music was Mr. Hewitt's principal pastime and enjoyment. An accomplished pianist and organist, he was organist and choir director for many churches.

Mr. Hewitt was a trustee of the Paterson Orphan Asylum, a member of the Friday Afternoon Music Club of Paterson, the Reformed Church in America, the Scottish Rite, and Past Master of Ivanhoe Lodge No. 88, F. and

---

[1] Memoir prepared by E. M. Lee, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 108 (1943), p. 1560.

A. M. He belonged to the American Institute of Architects, Passaic County Engineering Society, and State Association of County Engineers (New Jersey).

Mr. Hewitt was elected an Associate Member of the American Society of Civil Engineers on October 3, 1906, and a Member on March 5, 1912.

GEORGE HIGGINS, M. Am. Soc. C. E.[1]

DIED AUGUST 21, 1943

George Higgins was born in Borrisokane, Tipperary County, Ireland, on March 31, 1856, the son of the Rev. John Higgins, a Wesleyan Methodist minister, and Anne (Bournes) Higgins. His school days were spent in Abbeyleix, Newry, Dublin, Clonmel, and Wexford—all in Ireland.

In November, 1869, he left Ireland and arrived in Melbourne, Australia, in February, 1870. For a few years he was engaged in commercial, shipping, and banking work.

Mr. Higgins entered the University of Melbourne on March 31, 1875, and received the certificate of Civil Engineer in November, 1877. During 1878, he studied mining, metallurgy, and higher mathematics, while earning some fees for private teaching and for drafting work in the Crown Lands Department. He was awarded the Argus Scholarship in Engineering in February, 1879. Early in 1879, he entered the Victorian (Australia) Railways Department, doing office work and field work on railway surveys and later on railway construction. He also acted as engineer for contractors on the railways to Mudgee, Jerilderie, and Hawkesbury, in New South Wales, Australia.

In 1885 he directed operations for the erection and working of a large stone-crushing plant at Wandong to supply ballast for the North Western Railway Line in Victoria. From November, 1885, to June, 1888, as contractor's engineer, Mr. Higgins supervised the building of Prince's Bridge in Melbourne, and worked on the reclamation of the Elwood Swamp at St. Kilda, Australia.

In July, 1888, he visited California and arranged with the patentee to use a patented system of suction dredging for the construction and operation of a dredge in Australia. In August, 1888, he returned to Melbourne and constructed the dredge *Elwood.* Besides reclaiming the Elwood Swamp with that dredge, he supervised excavation of a canal and dock for the Railway Department of Victoria on the West Melbourne Swamp, the dredged material being used to reclaim adjacent land, later occupied by railway yards and sheds. The land on which the Yacht Club's building was erected at St. Kilda was also reclaimed from the sea by the *Elwood.*

During these operations with the *Elwood* and afterward, Mr. Higgins designed and superintended the construction of the suction dredge with which the Albert Park Lake, near Melbourne, was deepened and adjacent low lying land was reclaimed. He also designed and constructed in Sydney, Australia, machinery for the suction dredge, *Groper,* which has been used by the New South Wales government at both Sydney and Newcastle, Australia. Later, he planned cutting machinery for the government suction dredge, *Dictys,* which operated in soft sandstone on the Richmond River in New South Wales. Suction-dredging machinery was also designed by Mr. Higgins for the Queensland (Australia) government, for dredging contractors in Queensland, and for the contractors on the Adelaide (Australia) outer harbor. He was employed by the firm of William Simons and Company, of Renfrew, Scotland, to design cutting machinery for dredges operating in Durban, Union of South Africa, and Rangoon, Burma.

---

[1] Memoir prepared by G. O. Higgins, on service with United States Foreign Economic Administration in South Pacific.

In New Zealand, Mr. Higgins designed dredging machinery for the Otago Harbour Board and for a west coast gold dredging company. From 1905 until 1922, he lectured on civil engineering and (for about five years) on surveying in the University of Melbourne, being appointed dean of the faculty of engineering and acting professor for one year. His private practice during these seventeen years consisted mainly in advising the government of Victoria in connection with accidents on railways at Richmond, Australia, and near Castlemaine, Australia. He was a member of a board of inquiry appointed to examine a proposal for using minting machinery to manufacture cartridges and also of a board which reported to the Victorian government on silt disposal.

Mr. Higgins contributed to various technical journals, and was the author of two books, "Centrifugal Pumps"[2] and "Water Channels."[3] He translated literature on the water hammer from Italian and "Chambres d'Équilibre"[4] from French. Much of the years 1927 and 1928 was devoted to the preparation of a third book on "The Flow of Liquids in Pipes." However, this work was suspended when he was appointed engineer to the Warrnambool Harbour Board in Victoria, early in 1929. He was in England when this appointment was made, and came to Australia by the first steamer. He prepared a scheme for a harbor at Warrnambool, based on surveys and borings which he supervised. The plan was approved by the Harbour Board, by the Victorian Department of Public Works (to whom it had to be submitted), and by the State Executive Council. At this stage, the Victorian government declared its inability to provide funds for the work. His engagement with the Harbour Board terminated in the middle of 1930.

After 1930, instead of completing his third engineering book, Mr. Higgins devoted most of his time to lecturing and writing on economic subjects, being impressed with the urgency of the financial situation—the virtual financial collapse not only of Australia but of many other countries. His conviction that the American economist, Henry George, had discovered the root cause of financial collapse, poverty, unemployment, and war led to Mr. Higgins participation in the work of organizations which proposed to apply practically the methods recommended by Mr. George. Mr. Higgins also began to write a book on "The Natives' Land in Africa."

---

[2] "Centrifugal Pumps," by George Higgins, Lockwood, London, 1926.

[3] "Water Channels," by George Higgins, Lockwood, London, 1927.

[4] "Théorie des Chambres d'Équilibre," by J. Calame and D. Gaden, Gauthier-Villars, Paris, 1926.

In addition to his trip to California, Mr. Higgins spent about two years in Great Britain, which included several visits. While correcting proofs for his published books and preparing material for the third, he lived for nearly twelve months in Rome, Italy. He visited Holland, Belgium, Germany, Russia, France, Cape Town (Union of South Africa), Durban, Colombo (Ceylon), and all the Australian states—his chief interest when traveling being harbor works.

Always interested in professional affairs, Mr. Higgins was a member of the following engineering associations: The Victorian Institute of Engineers (former president), the Melbourne University Engineering Society (former president), the Institution of Civil Engineers of England, the Verein Deutscher Ingenieure of Germany from 1902 to 1914 (attached to the Wurtemburghischer Bezirksverein), the International Association for Testing Materials, the Symposium on Water Hammer of New York, N. Y. (honorary member), and the International Congress of Navigation. In addition, Mr. Higgins belonged to the following social and civic organizations: The Town Planning Association of Victoria, the Australian Forest League (committee of the Melbourne Branch), the League of Nations Union of Melbourne (member of the council), the Australian Student Christian Movement (vice-president of the senior branch), the Melbourne Branch Peace Society, the Melbourne University Rowing Club (life member), the Yorick Club of Melbourne, the Malvern Chess Club of Melbourne, the Royal Melbourne Golf Club, the Metropolitan Golf Club of Melbourne, various golf clubs in Sydney and New Zealand, The Henry George Club and The Henry George League (both of Melbourne), and the English League for the Taxation of Land Values. As he grew older, Mr. Higgins became increasingly deaf, and he was unable to participate actively in meetings of the various groups.

Concerning Mr. Higgins' personality and character, a former student, C. Carre-Riddell, wrote:

> "There is another most important part of his life, of which there is no record, except in the hearts and memories of those he met, particularly among his old students. Most of us met him for the first time as leader of the annual survey camps which were our introduction to the life of engineering on which we had then embarked.
>
> "After the field work of the day, during and for half an hour after the evening meal, before the night's recording and checking of results commenced, he would sit and talk with us. During these talks he taught us much without appearing to do so. Incidents in his own experience, difficulties overcome, many a tale, sometimes against himself, but so often containing a moral partly hidden in dry humour, taught us much in those happy evenings.
>
> "We learnt then that engineering means much more than the mere calculation of strength and stress and quantity of earth or rock to be excavated, or of cost per cubic yard or linear mile; he taught us how important were those things which cannot be weighed or measured, how success and

failure so often depend on human nature. He showed how we would be dealing quite as much with men as with steel and stone. Men of all types, some employees under our control, some such as town councillors who would be in a sense our employers, and the engineer stood between, responsible to both: To one for carrying out the work cheaply and efficiently, and to the other for a fair deal with strict, but not stern, discipline.

"His teaching all led up to this that the engineer must show both sides that he knew his job and intended to do it to the best of his ability, that all men could approach him and would get a courteous hearing either to complaint or suggestion, and above all that he did what he considered just, honest and right in all circumstances.

"So often I have heard the remark from one of his hearers after such a talk 'George is a real white man.' There could be no higher compliment and none deserved it more.

"A great English poet [Tennyson in 'Ulysses'] has said that 'I am a part of all that I have met' and throughout this land and scattered in many other places there are men who, having met and absorbed a part of him, are better engineers but, above all, better men, for having met George Higgins.

"As long as I live, I will be grateful that I am one of them."

On August 29, 1892, in St. George's Church, Malvern, Melbourne, Mr. Higgins was married to Beatrice Elizabeth Shuter. He is survived by his widow and two sons, the writer and C. G. Higgins, who is serving with the Royal Air Force in the European theater.

Mr. Higgins was elected a Member of the American Society of Civil Engineers on October 2, 1907.

FRED KEATING HILT, M. Am. Soc. C. E.[1]

DIED JULY 11, 1944

Fred Keating Hilt was born at Perryville, Md., on April 30, 1872, the son of Oscar and Zoe (Owens) Hilt. He was born into construction work, as his father, who came originally from Maine, was a contractor and bridge builder and was engaged in the construction of the old double-deck iron railroad bridge over the Susquehanna River from Perryville to Havre de Grace, Md., when he met Zoe Owens, a resident of Perryville.

Young Hilt's boyhood home was in Rensselaer, N. Y., where he received his preliminary education and then attended and was graduated from Rensselaer Polytechnic Institute at Troy, N. Y., with the degree of Civil Engineer in 1894. After graduation, for about one year he was with his father on general heavy construction, including some cofferdam work. He then was employed by the Hilton Bridge Construction Company of Albany, N. Y., as a template maker and draftsman.

---

[1] Memoir prepared by B. S. Murphy, Mech. Engr., Jersey City, N. J.

In August, 1896, he began the type of engineering work that he was to do so successfully for many years, when he went with the U. S. Corps of Engineers, first as a civilian instrumentman and later as chief of hydrographic party on the upper Hudson River improvements. Since this was seasonal employment, Mr. Hilt spent his winters as inspector of masonry on the Erie Canal improvements for the New York State Superintendent of Public Works.

In February, 1901, Mr. Hilt began to specialize in tunnel work, continuing in this field until his death. His first engagement was with the Pennsylvania Railroad Company on the preliminary surveys and borings and then on the precise triangulations and topographical surveys for the New York (N. Y.) tunnels. In 1903 he was with the firm of Jacobs and Davies (Charles M. Jacobs [2] and John Vipond Davies,[3] Members, Am. Soc. C. E.), as an assistant engineer on the same type of precise work for the southern tunnels of the Hudson Companies (later Hudson and Manhattan Railroad Company) under the Hudson River from Jersey City, N. J., and Hoboken, N. J., to downtown Manhattan. Also, during this time he made the preliminary surveys for the proposed gas tunnel under the East River from Long Island to 111th Street in Manhattan.

With the beginning of construction on the Hudson and Manhattan tunnels, Mr. Hilt, as division engineer, continued in responsible charge of the alinement and field engineering during the building of the river tunnels, stations, and approaches of the northern division from Hoboken to 12th Street and Sixth Avenue in Manhattan. This project included 7.5 miles of underground and subaqueous railroad tunnels, the terminal at Hoboken, caissons at junction points, and the building of the stations at Christopher Street and 9th Street in Manhattan.

On the completion of this work, Mr. Hilt was transferred to the section extending from Exchange Place to the surface in Jersey City. This was extremely interesting construction as it was under what was then the main passenger line of the Pennsylvania Railroad into New York City and the tunnels extended through the fill of this four-track steam railroad. All this work was done by compressed-air tunnel construction methods until the roof of the tunnel was at street grade, with no interruption to the heavy steam railway traffic.

After the Hudson and Manhattan tubes were in full operation, Mr. Hilt was made works manager and division engineer, in charge of all heavy construction and tunnel structure repairs. During this period he designed and constructed an additional platform, about 350 ft long, with the necessary passenger passageways at the Erie Station in Jersey City. All this work was below water level in soft muck and sand, and construction was completed without closing off the station to the public or without interrupting train movement.

Mr. Hilt resided in Ridgewood, N. J., for a number of years and gave much time to voluntary work with the school board on construction matters.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXIII (1919–1920), p. 2236.

[3] For memoir, *ibid.*, Vol. 105 (1940), p. 1826.

On February 8, 1935, in Ridgewood, he was married to Mrs. May Lee. He is survived by his widow; a daughter, Janet (Mrs. Winthrop Foster), by a former marriage; and one grandson, Winthrop Foster, Jr.

Mr. Hilt was elected a Member of the American Society of Civil Engineers on November 28, 1916.

JOHN BENJAMIN HITTELL, M. Am. Soc. C. E.[1]

Died July 4, 1944

John Benjamin Hittell was born in Wilton, Iowa, the son of Lydia and Thomas Hittell. When he was very young, his parents moved to Allentown, Pa. He was graduated from Lehigh University at Bethlehem, Pa., with the degree of Bachelor of Science in Civil Engineering in 1887.

His first employment was with the Atchison, Topeka and Santa Fe Railway Company. He then went to Chicago, Ill., as an assistant engineer for the Town of Lake View which was annexed to the City of Chicago in 1889. He worked for the City of Chicago for fifty-one years. In 1941 he retired as chief engineer of streets in the Board of Local Improvements—a title that he received in 1901. Upon retirement from the service of the City of Chicago, Mr. Hittell formed the partnership of Grimes-Hittell, consulting engineers, with offices in Chicago.

During the forty years that Mr. Hittell was chief engineer of streets for the City of Chicago, he planned and supervised the construction of about 4,000 miles of city pavement which cost approximately $275,000,000. Some of the most important street improvements accomplished under Mr. Hittell's direction were the widening and paving (100 ft wide) of Ashland Avenue and Western Avenue. This work extended from the northerly to the southerly city limits. These two street improvements, 20½ miles long and 24 miles long, cost $26,000,000 and $22,000,000, respectively.

During the economic depression, Mr. Hittell prepared a large program of street improvements, eligible for the use of Federal Public Works Administration funds. He obtained these funds together with funds from the motor fuel tax to construct simultaneously twenty-six street improvements in various sections of the city, during 1937 and 1938. These were the first new pavements in the City of Chicago to be financed in this manner.

During the period that he served the City of Chicago, Mr. Hittell witnessed probably the most sensational rehabilitation of a system of streets ever to occur in any large city in the world. A sprawling city with millions of people, Chicago in 1900 had narrow, broken, cobblestone, wood-block, and macadam pavements, which were unsuited and inadequate for modern traffic. When he retired, the city had an almost complete renewal of pavements, with many important streets widened, extended, and unobstructed.

---

[1] Memoir prepared by Arthur Engh, Assoc. M. Am. Soc. C. E., and James E. Grimes, Chicago, Ill.

He was a member of Tau Beta Pi, past-president of the Illinois Society of Engineers, Inc., and one of the founders of the American Road Builders' Association.

On September 29, 1919, in Buena Presbyterian Church at Chicago, Mr. Hittell was married to Corinna Beatrice Williams. He is survived by his widow and one brother, R. James Hittell.

Mr. Hittell was elected a Member of the American Society of Civil Engineers on July 1, 1909.

ELMER THOMAS HOWSON, M. Am. Soc. C. E.[1]

Died September 1, 1944

American railway transportation systems long felt the impact of the mind and pen of Elmer Thomas Howson, western editor of *Railway Age,* editor of *Railway Engineering and Maintenance,* and editor of the "Railway Engineering and Maintenance Cyclopedia."[2] His keen analytical appraisal of men and methods, his dynamic presentation of fundamentals, and his ability to organize and inspire others resulted in his leaving accomplishments far exceeding those usually found in a busy life terminating at sixty years.

Elmer Thomas Howson was born near Clinton, Iowa, on May 23, 1884. He was the son of Thomas Henry and Anna Cora (Wessels) Howson. He died at Chicago, Ill., on September 1, 1944.

His early education was acquired in rural schools, which he attended until reaching high school age. The family moved to Clinton when he was thirteen years old, and Mr. Howson attended the Clinton High School, being graduated in 1902.

In the fall of that year he entered the College of Engineering of the University of Wisconsin at Madison, from which he was graduated with the degree of Bachelor of Science in Civil Engineering in 1906. The degree of Civil Engineer was conferred upon him by the University of Wisconsin in 1914. While in the university, he was an honor student, a member of Tau Beta Pi, and president of the civil engineers' society.

Early in life, Mr. Howson chose railway transportation as his specialty. Like many others with a similar leaning, he started at the bottom, pursuing the course that had been charted by his engineering training, and was willing to live and learn. However, since he was endowed with an unusual capacity for both living and learning, his advance was destined to be rapid—beyond what were his most ambitious hopes.

Probably he would have risen to a commanding post in the engineering councils of some great railway. However, fate had decreed a broader field for him, one that would embrace all railroads and all phases of railroading where his influence for higher standards and constant betterment would reach all ranks of railway men in all parts of the United States—the field of technical railway journalism in which he was destined to attain a position of pre-eminence.

---

[1] Memoir prepared by Louis R. Howson, M. Am. Soc. C. E.; Samuel O. Dunn, chairman of board of Simmons-Boardman Pub. Corp. and editor of *Railway Age;* and Neal D. Howard, editor of *Railway Engineering and Maintenance.*

[2] "Railway Engineering and Maintenance Cyclopedia," edited by E. T. Howson, Simmons-Boardman Pub. Corp., Chicago, Ill., 1st Ed., 1921.

While still at the University of Wisconsin, during his summer vacation in 1903, Mr. Howson was first employed on railway work by the Iowa and Illinois Railway (later the Clinton, Davenport and Muscatine). Returning to the same railroad during the summer of 1904, he was appointed instrumentman. After his graduation in 1906, he immediately became resident engineeer for the Chicago, Burlington and Quincy Railroad Company, soon advancing to assistant engineer on that railroad's heavy reconstruction work in Wisconsin and Illinois. In 1911 Mr. Howson was promoted to division engineer of the railroad's La Crosse division, with headquarters at La Crosse, Wis., in charge of maintenance and extensive second-track work. Having attracted the favorable attention of higher officers of the railroad, he was definitely on his way to still greater responsibilities when, early in 1911, he was asked to join the staff of the *Railway Age* (then the *Railway Age Gazette*). This publication needed a man of broad capabilities to give it further engineering prestige.

At first, Mr. Howson was reluctant to leave active railway service, since, by that time, he had acquired an absorbing love for railroading that was never to leave him. However, convinced that the opportunity opened broader horizons for that love, with a larger field for service, he became engineering editor of the *Railway Age* on February 1, 1911. In taking this step he was also influenced, no doubt, by an early interest in the journalistic field and an innate ability with the pen. In his school days, he had inaugurated a monthly high school magazine, of which he served as editor. At the University of Wisconsin he was editor of the *Wisconsin Engineer,* the publication of the Engineering College.

As the first engineering editor of the *Railway Age,* Mr. Howson soon became important, not alone through the pages of that publication (which immediately began to assume leadership in the coverage of current railway construction and maintenance practices), but also in the railway field generally. His influence was the result of his extensive traveling and insatiable desire to know railway men and to study their problems. Not satisfied, however, with the outlet which the *Railway Age* alone offered for disseminating engineering and maintenance information (the space available for covering the activities of each railway department was necessarily limited) and convinced that there was a field for an associated publication dealing primarily with matters relating to track, bridges, buildings, and water service facilities, he was soon promoting the creation or acquisition of such a publication. As a result, in June, 1916, the publisher of the *Railway Age,* the Simmons-Boardman Publishing Corporation, purchased the then outstanding publication in this field—*Railway Engineering and Maintenance of Way*—and incorporated it into the corporation's growing group of transportation publications under the name of *Railway*

Maintenance Engineer. Continuing as engineering editor of the *Railway Age,* Mr. Howson also became editor of this new publication, the name of which was subsequently changed, in 1923, to *Railway Engineering and Maintenance.*

In 1919, in recognition of the fact that his interests and activities transcended the field of railway engineering and maintenance, Mr. Howson was appointed to the newly created position of western editor of the *Railway Age;* and, subsequently, in 1936, he was elected vice-president, assistant secretary, and assistant treasurer of the Simmons-Boardman Publishing Corporation. In 1937 he was elected a director of the corporation.

As western editor of the *Railway Age* and directing head of *Railway Engineering and Maintenance,* Mr. Howson's principal and constant endeavor was to render maximum help to railway officers through the pages of these publications. He accomplished this purpose not only by reviewing current activities in the field, but also through his editorial writings, which were designed to stimulate constantly improved construction, maintenance, and operating practices.

In 1919, convinced that beyond the publications of his company there was still further opportunity to serve those concerned directly or indirectly with railway engineering and maintenance matters, Mr. Howson sponsored and was appointed editor of the first edition of the "Railway Engineering and Maintenance Cyclopedia," a volume treating all branches of railway construction and maintenance authoritatively. This was being revised for a sixth edition when he died.

Mr. Howson believed that there was no substitute for personal observation in securing information in the railroad engineering field. Accordingly, he traveled extensively on the railroads of the United States, Canada, and Mexico. His writings were authoritative discussions of the problems and accomplishments of these railroads. He watched with great interest the nationalization of railroads in Mexico and his last contribution to the *Railway Age,* which dealt with the problems of the Mexican railroads, was published after his death.

Through his multitude of connections, his extensive travels, and widespread observations of railroad practices, Mr. Howson obtained an unparalleled fund of practical information. To him, this information was not just something to acquire and retain—but to make available to others. He shared his knowledge freely with the men with whom he came in contact, either personally or through his writings; and, in return, he received and cherished the respect and intimate friendship of large numbers of railway engineering maintenance, operating, and executive officers.

In the interest of his profession as an engineer and railway editor, Mr. Howson had long been a member of many technical associations, societies, and clubs, always taking an active part in their affairs. Among these groups were the Illinois Section of the Society (President in 1927); the American Railway Engineering Association (a director, chairman of the arrangements committee, and chairman of the committee on cooperative relations with universities when he died); the American Association of Railroad Superintendents (chairman of the program and arrangements committee); the Western Society of Engineers (president in 1924–1925); the American Wood-Preservers' Association (president in 1932); the Roadmasters' and Maintenance of Way Association (president in 1934); the American Railway Bridge and Building Association (president in 1927); the Western Railway Club (for a number of years chairman of the program and arrangements committee); the National Conference of Business Paper Editors (president in 1925–1926); the Associated Business Papers, Inc., a national organization of the publishers of business papers (president in 1934–1935); and the Maintenance of Way Club of Chicago (charter member in 1921 and chairman of the program committee). In addition to his membership and activities in these technical associations and societies, Mr. Howson belonged to the following clubs in Chicago: The Union League Club, the South Shore Country Club, and the Chicago Engineers' Club.

Elmer Howson had limitless energy supported by a robust physique. His capacity for work was enormous. To be associated with him was a challenge. His habit of driving himself inspired others to do their best. He did not spare himself and expected others to follow his pace—a feat that was not always easily accomplished. However, he never expected of others more than he was ready to do himself.

Perfection in whatever he undertook was almost an obsession with Elmer Howson. He strove for it himself and inspired others to work for the same goal. He was impatient with careless or indifferent work, but was ever ready, through direction and encouragement, to assist others to exert their best efforts. He was particularly delighted with, and interested in, young men, and inspired them constantly to higher achievements and confidence in their ability. Although critical of inferior work, he was able to appraise and bring out the best in others and to organize the efforts of his staff so as to secure the most effective utilization of the potentialities of his associates.

From youth, Mr. Howson was an organizer and he never allowed an organization, once started, to lapse through inattention on his part. The numerous technical associations that he headed; the Howson Fellowship Bible Class, which he organized; the Howson annual family reunion, which he fostered; and even a long-standing association of his high school class members, which he helped to sustain—all testify to the fact that he felt a continuing responsibility for every activity in which he participated.

This cumulative sponsorship of many activities required time and energy in ever-increasing amounts, which in some way Mr. Howson managed to summon to his command. His counsel was sought and freely given to the many associations and societies in which he played so prominent a part. His administration of their affairs was uniformly aggressive and rich in accomplishments. Several associations largely owe to him their survival during the depression and their existence today as virile influences for the betterment of railway transportation services.

A vital force in the life of Elmer Howson was his deep and firm religious convictions. He was a lifelong member of the Methodist Church and was ever active in its service. Since 1911 he resided in Chicago and served the Woodlawn Methodist Church as a member of the board of stewards, chairman of the finance committee, chairman of the board of trustees, and lay delegate to the Rock River Conference. In many other ways, he devoted his time and energy to religious work.

In 1911 he organized and assumed leadership of a Young Men's Bible Class, which became one of the major activities in his busy life. Under his inspirational leadership, the class developed into one of the largest and most active in Chicago. In the thirty-three years of its existence prior to Mr. Howson's death, more than 10,000 men had been members of the class, and its influence is felt by men scattered throughout the world. In 1931 the class name was changed to the Howson Fellowship Bible Class. He continued as the class leader through all the years and gave much of his thought and energy to the class. Of all the many and varied activities in which he participated, the class which bore his name was perhaps the dearest to him.

On June 5, 1907, he was married to Mae McCulloh, who survives him.

Mr. Howson was elected an Associate Member of the American Society of Civil Engineers on May 28, 1912, and a Member on March 9, 1920.

HAROLD WALTON HUDSON, M. Am. Soc. C. E.[1]

DIED JANUARY 15, 1943

Harold Walton Hudson devoted the greater part of his active professional career to the direction of large engineering operations rather than to their design. He was more at home on the job in high boots and an old hat than at a desk in the office. His ability to deal with men and to supervise their activities won him a high place in the civil engineering and general construction field. He spoke and understood the language of the construction man. Despite his blunt and often gruff manner of speech, he was both liked and respected by all the men with whom he came in intimate contact on the projects he directed.

Mr Hudson was born in Pittsburgh, Pa., on September 29, 1874, the son of Thomas James and Elizabeth (Reilly) Hudson. He studied civil engineering at the University of Minnesota at Minneapolis for three years, and then left college to take up the railroad and general engineering work in the West, Midwest, and Southwest that doubtless gave him his love of the outdoors and construction camps. He was instrumentman on the Florence and Cripple Creek Railroad in Colorado and held various jobs with the engineering firm of Tuttle and Pike. In May, 1900, he joined the engineering force of the Missouri Valley Bridge and Iron Works and was sent to Tampico, Mexico, on wharf construction. A year later he returned to the United States to resume railroad work in the Southwest.

---

[1] Memoir prepared by V. T. Boughton, M. Am. Soc. C. E.

For a decade Mr. Hudson devoted himself largely to railroad work. In 1903 he inaugurated his long connection with the Pennsylvania Railroad Company, and its subsidiaries, being employed in various capacities for twenty-five years except for short intervals. After service as assistant engineer on the Philadelphia Division and a brief period in private practice, Mr. Hudson came to New York, N. Y., in November, 1906, as assistant engineer for the Pennsylvania Tunnel and Terminal Railroad Company on the Sunnyside Yards in Long Island, part of the great new terminal development of the Pennsylvania Railroad System. On the conclusion of that work, Mr. Hudson spent about a year on a power project in Tennessee, but in 1912 he returned to New York to become engineer of construction on the Hell Gate Bridge and its approaches. That position he held until May, 1917, when, as a Captain in the Engineer Reserve Corps, he was called into active service to command Company A of the 1st Reserve Engineers, later the 11th Engineers (Railway), U. S. Army.

Captain Hudson sailed with the 11th Engineers in July, 1917, but soon after the regiment reached France he was drafted by Brig.-Gen. W. W. Atterbury,[2] M. Am. Soc. C. E., then head of the Transportation Corps of the American Expeditionary Force (for whom Captain Hudson had worked while with the Pennsylvania Railroad Company), as one of the officers of his staff on the Transportation Corps. Captain Hudson served in this capacity until after the armistice, being promoted to the rank of Lieutenant Colonel. After the armistice he rejoined the 11th Engineers, returning as commanding officer of one of the two units into which the regiment was divided for transportation back to the United States. For his war service he was awarded the Purple Heart by the United States Government and was made a Chevalier of the Legion of Honor of France.

After World War I, Colonel Hudson was chief engineer of the Interstate Railroad Company in Virginia on location, surveys, and construction, from 1919 to 1924. Subsequently, he became superintendent of construction for Gibbs and Hill, engineers, of New York, on electrification of the Virginian Railway. On completion of that work he held the same position with Gibbs and Hill on the electrification of the Bay Ridge Division of the Long Island Railroad Company.

Leaving railroad work in 1928, Colonel Hudson went to the New Jersey State Highway Department to participate in the building of new highway approaches to New York City from the southwest. He took an active part in the selection of a high-level viaduct (later the Pulaski Skyway) for carrying the new highway in New Jersey between Newark and Jersey City, and was engineer in charge of construction. After this project was completed, he was appointed Assistant State Highway Engineer, holding this position until March, 1934, when he resigned to become chief construction engineer of the Triborough Bridge Authority on the Triborough Bridge and the Bronx-Whitestone Bridge. He later joined the engineering firm of Madigan-Hyland, of New York, remaining until his death on January 15, 1943.

---

[2] For memoir, see *Transacations*, Am. Soc. C. E., Vol. 101 (1936), p. 1518.

From 1939 to 1941, Colonel Hudson was a Director of the Society. In 1937–1938, he served as president of the Metropolitan Section.

Colonel Hudson was elected an Associate Member of the American Society of Civil Engineers on May 3, 1905, and a Member on September 3, 1912.

MARTIN JOACHIMSON, M. Am. Soc. C. E.[1]

DIED FEBRUARY 7, 1944

Martin Joachimson, the son of Fritz and Bertha (Riegner) Joachimson, was born in Breslau, Germany, on June 27, 1867. He was educated at the Breslau Gymnasium, and received the degree of Mechanical Engineer from the College of Mechanics in Berlin, Germany, in 1892.

After his arrival in New York, N. Y., he worked for the Electric Construction and Supply Company from 1893 to 1895. In 1895 and 1896 he was assistant engineer for the American Sugar Refining Company at Baltimore, Md. He served as chief engineer of Koster and Beal's Theatrical Enterprises of New York in 1896 and 1897. From 1897 to 1904 he was employed as mechanical engineer by R. Hoe and Company, manufacturers of printing presses, in New York City.

Mr. Joachimson entered the service of the City of New York in 1904, under the civil service title of draftsman, in the Department of Bridges (which in 1916 became the Department of Plant and Structures and finally was merged into the present Department of Public Works on January 1, 1938). Within a few years he was promoted to the grade of assistant engineer.

The department had under its jurisdiction many movable bridges of the swing-draw and bascule types and the mechanical and electrical equipment for these structures soon came within the scope of Mr. Joachimson's work. Many movable bridges were built by the department, for which Mr. Joachimson designed all machinery and electrical equipment. Among these were the University Heights, the Eastchester, the Greenpoint Avenue, the Metropolitan Avenue, the Roosevelt Avenue, the Eastern Boulevard, and the Westchester Avenue bridges.

The Department of Plant and Structures also constructed several garbage incinerators and a number of other city plants. Mr. Joachimson had charge of the design of the service installations. In 1924 Mr. Joachimson was promoted to the newly created office of engineer of equipment which he held with distinction until his retirement at the age of seventy one, on July 1, 1938.

Mr. Joachimson was both an expert in the field of mechanical engineering and a competent structural engineer. In his earlier years in the Department of Bridges, he worked on general bridge design. Mr. Joachimson also was a patent attorney, practicing as often as his regular duties permitted. After his retirement from the department he maintained an office, for several years, as consulting engineer and patent attorney.

---

[1] Memoir prepared by Isidore Delson, M. Am. Soc. C. E.

He found time for the hobby of photography and also for extensive travel in the United States, Canada, South America, and Europe. After his retirement he spent his winters in Florida. Mr. Joachimson was an active member of Beethoven Lodge, Free and Accepted Masons, of New York. He belonged to the Society of Professional Engineers.

On November 4, 1900, he was married to Lena Kallman of New York City. He is survived by his widow; by his daughter, Beatrice (Mrs. Fred Behr); by two grandchildren, Donald and Cecily Behr; and by a sister, Clara (the widow of Dr. J. Leon Lascoff).

Mr. Joachimson was elected a Member of the American Society of Civil Engineers on March 4, 1914. He became a Life Member in January, 1939.

FRANK MINITREE JOHNSON, M. Am. Soc. C. E.[1]

DIED MARCH 27, 1944

Frank Minitree Johnson was born at his paternal grandfather's home near Berryville, Va., on November 4, 1872. His parents were Robert Marshall and Katherine (Minitree) Johnson, both descendants of well-known Virginia families. His family home was in Washington, D. C., where his father was president of the Metropolitan Iron Works.

F. V. Hayden, then head of the U. S. Geological and Geographical Survey of the Territories, in the eighteen seventies, was a frequent visitor at the Johnson home. Young Frank as a small boy was fascinated by Dr. Hayden's experiences in the West, and he would ask numerous questions about the survey work. From these contacts Mr. Johnson acquired his interest in the outdoors and in survey work.

Mr. Johnson was educated in private schools in Washington, D. C., and was graduated from Central High School. He then attended the Corcoran Scientific School of the Columbian University (later George Washington University) for a year. For the next five years he was employed on various engineering jobs, including two years as a draftsman at the Cramp shipyards in Philadelphia, Pa.

In 1895 the U. S. Geological Survey began its subdivision of the lands of the Five Civilized Tribes in the Indian Territory, and, welcoming an opportunity to do survey work in the West, Mr. Johnson, in September, 1895, joined that organization as an axman on one of the field parties. A few months later he was advanced to surveyor in charge of a field party and continued in charge of various field parties until the completion of the field work in June, 1898. For the next five months he was engaged on office computations, and resigned on November 30, 1898.

---

[1] Memoir prepared by Robert Follansbee, M. Am. Soc. C. E.

As a result of his experience in making public land surveys, he was appointed an examiner of surveys in the General Land Office in March, 1899, and during 1899 and 1900 he spent the greater part of the time in New Mexico in connection with the survey of the Las Vegas Grant. Because of his friendliness and genuine interest in people, Mr. Johnson acquired a wide acquaintance with many old timers who were instrumental in shaping New Mexico's history. Mr. Johnson continued as an examiner of surveys engaged on examinations, engineering investigations, and special reports, chiefly in the Rocky Mountain area, until April, 1905, during which period he spent a six-month leave of absence abroad. While in Cairo, Egypt, he met Major Edwards, a British engineer in charge of making surveys for the enlargement of the Aswan Dam, and joined the Edwards party for a few months.

In 1905 the Shoshone Indian lands in Wyoming were to be subdivided preparatory to being opened for settlement, and, under the system then in effect, the work was to be done by private surveyors under contract. This was a project of considerable magnitude, and, in April, 1905, Mr. Johnson resigned from the General Land Office and opened an engineering office in Cheyenne, Wyo., chiefly for the purpose of making those surveys. Upon the completion of that work, which was done in record time, due to the early date at which the lands were to be allotted, he resurveyed lands in western Wyoming within the Union Pacific Land Grant, and also made subdivisional resurveys and determination of the boundaries of private lands, title to which had passed from the government. During these years in Wyoming, which continued until 1910, Mr. Johnson was able to settle many long-standing disputes between stockmen and settlers over the limiting boundaries of their holdings. This was accomplished not only because of his familiarity with the engineering problems involved, but also because of his complete understanding of human nature and its many frailties. He had the rare gift of being able to instil, in those affected, confidence in the fairness of his decisions.

In 1910 Congress, to meet more adequately the increasing need for public land surveys to provide for the rapid settlement then taking place and because of the increasing difficulty in obtaining contracts within authorized rates of compensation, abolished the old contract system, and directed the General Land Office to make future land surveys with its own personnel. From his experience both as an examiner of surveys for the General Land Office and later as a contract surveyor, Mr. Johnson was eminently fitted to head the new organization. Accordingly, in July, 1910, he was appointed U. S. Supervisor of Surveys to organize the Cadastral Engineering Service, the personnel of which consisted of former examiners of surveys and contract surveyors who had been previously associated with him. Headquarters was established in Denver, Colo., and within a short time thirteen regional offices were established in the public land states and Alaska.

Beginning with a dozen chiefs of field parties, the number was increased to one hundred and sixty chiefs of field parties by 1915. At first the Cadastral Engineering Service confined its activities to making the field surveys, and the office work connected with preparing the land plats was under the Surveyor General in each public land state. This division was not wholly satisfactory, and in 1925 Mr. Johnson was largely instrumental in having legislation enacted which abolished the position of Surveyor General and transferred the organizations to the Cadastral Engineering Service, thus bringing into one organization both the field and the office work. Under Mr. Johnson's wise leadership the land surveys were raised to a high standard of accuracy without materially increasing the cost of the work. During those years many seemingly unsurmountable obstacles were encountered, but through his efforts these crises were overcome. As a result of his genuine interest in people, his office door was always open to the lowest field assistant, who came out feeling that his chief was very much interested in his welfare. Mr. Johnson had the priceless attribute of inspiring loyalty in his associates who have been unanimous in giving him a major part of the credit for the successful organization and operation of the Cadastral Engineering Service.

Paying tribute to Mr. Johnson, the Secretary of the Interior, Harold L. Ickes, stated:

> "The death of Mr. Johnson is a distinct loss to the Government which he served so long and so well. Not only was he recognized as an outstanding authority on public land matters, but the skill and painstaking care with which he installed in 1911 (1910) and supervised until the time of his death the Government's Cadastral Engineering Service, will stand as a lasting monument to his memory."

On October 17, 1917, Mr. Johnson was married to Lucy E. Barham, of Texas, who survives him. This was a happy marriage, and, in the spirit of southern hospitality, the Johnsons kept a delightful open house for the officers of the Cadastral Engineering Service and for their many friends among the engineers.

One of Mr. Johnson's diversions was the study of history, particularly that of the West, and because of that study, as well as because of his many years of experience, he was an authority on the settlement of the West. During his earlier years, particularly, he knew some of its most colorful as well as notorious characters, and toward the latter he showed the tolerance, forbearance, and kindness of heart which he always felt toward his fellow men.

Mr. Johnson was deeply interested in boys approaching manhood and was ever ready to counsel and advise them against the pitfalls of life. He derived great satisfaction from giving six boys a college education.

Mr. Johnson was elected a Member of the American Society of Civil Engineers on August 29, 1927.

FRANK RHYMAL JUDD, M. Am. Soc. C. E.[1]

DIED MARCH 19, 1944

Frank Rhymal Judd was born in Hamilton, Ont., Canada, on May 28, 1882, of English parentage, the son of Albert Judd and Eliza Jane (Dillon) Judd. Through naturalization he became an American citizen on October 14, 1904. His father was a veteran railroad man in England, British India, and, subsequently, in Canada and the United States.

When Mr. Judd was young, his parents moved from Canada to Chicago, Ill. His boyhood days were largely spent in that city, and he received his education in Chicago. Upon being graduated from the Forrestville Grade School, he enrolled in the Chicago Manual Training Institute where he took a preparatory engineering course, including shop practice, being graduated in June, 1899. He later supplemented this training with courses in civil engineering, bridge engineering, and mechanical engineering.

After his graduation from the Chicago Manual Training Institute, he obtained employment in the Pullman Company Shops at Chicago. In November, 1899, he entered the service of the Illinois Central Railroad Company as a draftsman. During his employment with that company he held positions at various times as a chainman, rodman, instrumentman, structural designer, chief draftsman, assistant engineer, and Engineer of Buildings. With the exception of about ten months, when he worked as an instrumentman on a survey in Texas for the Chicago, Rock Island and Gulf Railway Company and as a draftsman with the Crane Company in Chicago, his entire professional career was with the Illinois Central Railroad Company.

Mr. Judd was appointed Engineer of Buildings for the Illinois Central Railroad Company in November, 1915, and held this position until ill health caused his retirement on August 31, 1943. While holding this position, he was in charge of the design and construction of all buildings on the railroad system and responsible, among many other projects, for the design and construction of the important railroad shops at Paducah, Ky., and Markham Yards, Chicago; water storage reservoirs; the passenger and freight stations at Baton Rouge, La.; the passenger stations at Champaign, Ill., and Jackson, Miss.; the railroad company's nine-story office building at 63d Street in Chicago; and levee protection for the railroad company's properties at New Orleans, La.

In addition to his membership in the Society, Mr. Judd belonged to the American Railway Engineering Association and the American Society for Testing Materials. While a member of the American Railway Engineering Association, he served on various committees, was chairman of Committee No. 6 for buildings, and was responsible for the preparation of specifications for railway buildings, which are used extensively on railroads in the United

---

[1] Memoir prepared by W. Raynes, Chf. Clerk, Bldg. Dept., Ill. Cent. R. R. Co., Chicago, Ill.

States. He was licensed to practice as a structural engineer in the State of Illinois, as a civil and structural engineer in the State of Indiana, and as a civil engineer in the State of Louisiana.

Mr. Judd enjoyed playing tennis and lawn bowling and took a keen interest in following the tennis championship matches. Interested in singing, at various times he sang in church choirs. He was an Episcopalian. He was a member of Garden City Lodge, Ancient Free and Accepted Masons No. 141, Chicago; Member of Ancient Scottish Rite of Free Masonry of Valley of Chicago, Thirty-Second Degree; member of Medinah Temple, Ancient Arabic order, Nobles of the Mystic Shrine, Chicago.

On September 27, 1910, in Chicago, he was married to Janet Gilmour MacLeish. He is survived by his widow and two daughters, Elizabeth Janet (Mrs. Holbrook P. Frazier) and Marjorie Jane (Mrs. Walter S. Smith, Jr.).

Mr. Judd was elected an Associate Member of the American Society of Civil Engineers on March 2, 1909, and a Member on September 8, 1941.

JULIUS KAHN, M. Am. Soc. C. E.[1]

DIED NOVEMBER 4, 1942

Julius Kahn was born at Münstereifel, Germany, on March 8, 1874. His parents, Joseph and Rosalie (Kohn) Kahn, brought their gifted children to America in 1881, settling in Detroit, Mich. This immigrant family of six sons was destined to influence greatly the architecture and building construction of many lands.

Julius Kahn was educated in the public schools of Detroit and at the University of Michigan, in Ann Arbor, from which he was graduated in June, 1896, with the degree of Bachelor of Science in Civil Engineering. Three years later the University of Michigan awarded him the degree of Civil Engineer.

During the three years after his graduation (June, 1896, to October, 1899), Mr. Kahn supplemented his theoretical engineering education by drafting and field work with (1) Union Bridge Company of Athens, Pa., (2) Bureau of Yards and Docks, U. S. Navy, and (3) C. W. Hunt Company, New York, N. Y.

Julius Kahn had a keen interest in Japan throughout most of his adult life. His first trip to that country was made in 1899, when he went to Tokyo to join the engineering staff of Frazar and Company. While employed by C. W. Hunt Company in New York, he received an offer through E. W. Frazar to become engineer on the development of a sulfur mine on the Island of Etorofu-jima in the Kurile group. Mr. Kahn accepted this position with his usual enthusiasm. He spent most of 1900 on that assignment, which he completed successfully. The experience had a pronounced bearing on his later life. He studiously acquired a knowledge of the Japanese language. In addition, he noted the differences between Japanese and American ideals and morals.

---

[1] Memoir prepared by O. W. Irwin, Assoc. M. Am. Soc. C. E.

Mr. Frazar was so impressed with Mr. Kahn's zeal, enthusiasm, and ability, especially in mathematical analysis, that he offered him another engagement, but at the same time recommended that he return to the United States where his unusual ability should assure him a successful career.

On returning to Detroit in January, 1901, Julius Kahn became associate partner to his older brother, Albert Kahn. This was the beginning of a lifetime team in America's construction era: Julius Kahn, the inventor and manufacturer, and Albert Kahn, the artist and architect, both specializing in industrial construction.

The young engineer and the young architect pioneered in concrete and reinforced concrete. Julius Kahn soon became aware of the diagonal tension problem in this new building material when subjected to bending. His solution was to attach shear members rigidly on the main reinforcing bar ("Kahn Trussed Bar"). The success of the idea was first demonstrated on the Agricultural Building of the University of Michigan in Ann Arbor.

To promote the "Kahn System" of construction, the Trussed Concrete Steel Company was incorporated in October, 1903. The brothers and a few friends furnished the modest capital required (about $55,000), and Julius Kahn was elected president and general manager. When it became evident that the average contractor would not risk his reputation by building in "mud reinforced with whiskered rods," Mr. Kahn organized the Concrete Steel and Tile Construction Company to do the field work, often giving bond to keep the structure standing for an initial period of five or more years. This was the modest beginning of a steel fabricating business which reached a volume of about $50,000,000 per yr under Mr. Kahn's guidance.

In spite of his financial success, Mr. Kahn desired recognition as an engineer rather than as a business executive. There was always a drawing board in his home and he was constantly refreshing his memory on engineering matters. Always active himself, he questioned the ability of any man who did not display energy and enthusiasm. He had confidence only in a draftsman who worked in his shirt sleeves.

As president of the Trussed Concrete Steel Company, later the Truscon Steel Company, Mr. Kahn was a frequent visitor at the application desk of the U. S. Patent Office. From August 18, 1903, to April 9, 1940, seventy-four patents were issued in his name. Scores of others, issued in the names of his employees, bear the imprint of his versatile mind.

Among the innovations evolved by him may be mentioned:

1. The use of clay fillers between reinforced concrete floor joists.
2. The substitution of permanent sheet steel fillers for clay tile to reduce the dead weight of the floor and decrease the number of joists.
3. The use of expanded sheet steel (known as metal lath) as a base for plastering and as concrete floor slab centering.

4. The use of united steel windows, the beginning of the present large steel window and steel partition industry.

5. The development of light steel joists for floors, ranging from the original double-channel "metal lumber," cold-formed from steel strip, through the spot-welded plate girder from strip, to the so-called "bar joist" and the very light "nailer joist."

6. The planning of many load transfer and anti-crack devices for use in concrete pavements.

7. Composite steel and concrete beams, the structural shapes to carry the construction loads and then to serve as reinforcing for the concrete after the latter had set—a system later used extensively on subway and building construction.

8. The use of reinforced concrete for railway cross-ties.

In the miscellaneous fields covered by Kahn patents are improvements in: Steel hangers for wood joists, expanded metal for slab reinforcement, concrete piles, stair treads, shaft hanger supports in sash hanging and operating mechanisms, screeds for anchoring wood floors to concrete, electric welding machines, expanded steel poles and towers for transmission lines, pressed-steel tunnel-liner plate, sound-excluding windows, highway traffic markers, sheet steel culverts, and even thread protectors. Thirty seven of the seventy-four patents, most of them basic, were issued in eleven years from 1904 to 1914. The exploitation of these patented ideas contributed much to the early growth and financial success of the company.

Mr. Kahn's first love was devising new forms of reinforced concrete. The structural frameworks of many of Detroit's auto manufacturing plants are monuments to his ingenuity and to his trust in this new material. He created his own design formulas for many a solid flat slab, with or without dropped panels, even raising the panel around the column head. He originated the so-called "cantilever" floor slab, very arbitrarily selecting points of inflection which more mathematical studies later confirmed. He was never more thoroughly "at home" than when, waiving aside a draftsman who was floundering in his own mathematics, he would take the stool and sketch in how the problem should be solved.

Mr. Kahn again became interested in Japan in 1910, when the Trussed Concrete Steel Company, after becoming successful in the United States, organized an export department and began to ship its products to foreign markets. In that year the company sent its first representative to Japan. Soon after the end of World War I, the Truscon Steel Company decided to establish a factory in Japan for the manufacture of steel building materials. The plant was built at Kawasaki between Tokyo and Yokohama and the enterprise was successful from the start. At times more than a thousand people were employed and the capital increased from 500,000 yen in 1910 to 5,000,000 yen in 1941. The factory was wrecked in the great earthquake of 1923, but was soon rebuilt on a larger scale and became Japan's largest enterprise of its kind.

In 1934 Mr. Kahn visited Japan again for the purpose of negotiating a merger between the Truscon Steel Company of Japan and a competing company which was owned by the great Mitsui Company. This transaction was concluded satisfactorily and resulted in the formation of the Oriental Steel Products Company which continued to operate successfully until the start of World War II.

Mr. Kahn made lasting friendships with a number of Japan's business leaders whom he liked to entertain in his spacious home, whenever they visited the United States. He often expressed sympathy with what he considered their legitimate aspiration to control and operate their own industries, but was deeply disappointed at the growing military control and nationalism in Japan.

In 1914 the headquarters of Truscon Steel Company were moved from Detroit to Youngstown, Ohio, in order to be near the sources of steel supply. Local fabricating shops were gradually established in eighteen other cities, from Boston, Mass., to Los Angeles, Calif., and from Minneapolis, Minn., to Jacksonville, Fla. Under Mr. Kahn's guidance the company became a vast training school for reinforced concrete engineers. Many a structural engineer was given a real postgraduate course in building design and construction, not to mention salesmanship, in the Youngstown Home Office, before being transferred to one of the more than forty sales offices. Many later "graduated" into responsible positions, with consulting engineers and with contractors.

As an industrialist, Mr. Kahn recognized his social responsibility—beginning with financial assistance to deserving and promising students and often to messengers and office boys. The company early adopted incentive wage plans. Departmental heads were rewarded with liberal bonuses, based on over-all company profits. Machine operators received extra payments for output in excess of 80% of the rated capacity of the machine. Keymen named their own beneficiaries in large life insurance policies, the premiums being paid by the company. District sales managers earned handsome bonuses as their district profits exceeded their district sales expenses. Attractive prizes (usually cash) were offered in monthly sales contests where the accredited "points" were computed on each sales contract in proportion to the estimated profit in the contract. The rivalry to excel was intense, but no employee disregarded the president's motto "all for one, one for all."

Among other social ideals, Mr. Kahn early instituted "Safety" as the factory slogan. He felt that, to avoid accidents in the plant, home conditions must be favorable and encouraged his supervisors to interest themselves in the family problems of their subordinates. The company was among the first to adopt group insurance, both accident and life, to alleviate financial worry in the homes of its employees. A full-time attorney was available gratis to employees to help them with any real or imaginary legal problems. Many a mortgage foreclosure and some incipient divorces were prevented. Employees were protected in auto and streetcar accidents.

The Truscon Laboratories in Detroit, created in 1906 during the earlier pioneering days of reinforced concrete construction, also enjoyed Mr. Kahn's active leadership. The laboratories, however, were quite independent of the Truscon Steel Company. Mr. Kahn, with his scientific approach, quickly recognized the need for a laboratory not only to test Portland cement but also to provide technical research and leadership in the development of basic concrete practice. The laboratories made outstanding contributions in improving the methods of testing and inspection of Portland cement and in standardizing the technique of proportioning, placing, and handling concrete. Later the need of various dampproofings, waterproofings, and special technical coatings for concrete became apparent to Mr. Kahn, and the laboratories initiated and completed the research involved in the development of a complete line of specialized products for use with concrete construction. Although Mr. Kahn assigned the development work to his staff of chemists and laboratory technicians, he maintained a close interest and his great vision and tireless energy were constant stimulants to the laboratory organization.

In this field Mr. Kahn's genius for appropriate and effective advertising flowered. He was a firm believer in the efficacy of printer's ink and the drawing power of beautiful pictures. He made it easy for the prospective buyer to ask questions by tearing the corner off the advertisement. He preached that no question should go unanswered, no matter how illiterate the inquirer, and he boasted that some of his best sales resulted from following up postal card inquiries.

In 1935 Mr. Kahn and the directors arranged for the stockholders of the Truscon Steel Company to exchange their stock for that of the Republic Steel Corporation on a basis which Mr. Kahn felt was very favorable to the stockholders. At that time the Truscon Laboratories separated entirely from the parent company, and Mr. Kahn became chairman of the board of the laboratories, continuing until his death.

When the exchange of Truscon stock was completed in October, 1935, Mr. Kahn resigned the presidency of Truscon Steel Company to become vice-president of Republic Steel Corporation, in charge of product development, and moved to Cleveland, Ohio. To assist in this work he requisitioned several of his former associates in the Truscon Steel Company, and during the next four years he made many trips to the U. S. Patent Office.

By 1939 Mr. Kahn was homesick for the active commercial life, and, consequently, aided (with a substantial loan) four of his "boys" to incorporate the United Steel Products of Wooster, Ohio. He was a regular visitor at the Wooster plant and was very free with advice and assistance. It is related that he arrived one morning, with tickets in his pocket for a Mediterranean cruise for Mrs. Kahn and himself. When he learned that his "boys" were striving to design and sell a large order of pressed steel plates in Honolulu, Hawaii, he telephoned to Cleveland to cancel the cruise and asked Mrs. Kahn to be ready to start that evening for San Francisco, Calif., and Honolulu. When the design was completed and the order secured, the Kahns vacationed in Hollywood, Calif., for a few weeks.

After his resignation from Republic Steel Corporation in 1939, Mr. Kahn continued to live in Cleveland, looking after his many investments. He retained his connection with the Truscon Laboratories and became president of the Kahn Realty Company, both in Detroit. His office in the Terminal Building in Cleveland was the focal point for scores of ex-Truscon men, until his too early death. His visitors were never disappointed in his friendly interest, and always were surprised by his marvelous memory for mutual interests of bygone years.

Probably his most outstanding characteristic, that impresses one who has been associated with Julius Kahn for many years, was his truly democratic spirit. Notwithstanding his success in his chosen field, both from the professional and materialistic viewpoints, he remained, in the truest sense of the word, a real democrat. Any one in his organization—no matter how lowly his position—could approach and see Mr. Kahn at any time. In fact, as success crowned his efforts, the democratic spirit inherent in Mr. Kahn seemed to expand, and his greatest joy and relaxation seemed to come from an association with the men who had spent practically their entire business careers with him.

His keenness of mind and readiness in making decisions marked him as a true leader of men. In addition, he had a thirst for knowledge in every field and a mental capacity able to absorb an unlimited amount of information, which truly made him one of the intellectual giants in the steel industry of his generation.

His inventive genius, combined with his determination to succeed, gave him the incentive to contribute enormously to the introduction and progress of a new type of construction—reinforced concrete—in the building field. His daring in design and his willingness to experiment formed a combination, the results of which reached to all corners of the world. The Marlboro-Blenheim and the Traymore hotels at Atlantic City, N. J., the trestle of the Chesapeake and Ohio Railway Company at Richmond, Va., and reinforced concrete structures throughout the United States and other parts of the globe stand as lasting monuments to his genius—far more enduring than any tribute of words.

Julius Kahn was a member of the American Society of Mechanical Engineers at the time of his death.

On December 24, 1903, Mr. Kahn was married to Margaret Kohut of New York. As usual, he was most indifferent to matters of personal comfort and welfare. For his approaching wedding he neglected the buying of appropriate clothes and a ring until the day he was leaving Detroit for New York to be married. The charm, tact, and beautiful cooperation of his wife were decided factors in his success. It was not unusual for Mrs. Kahn to play the part of hostess at dinner while her husband was trying to solve an engineering problem with a pencil on the white tablecloth. Into this perfect home were born two daughters, Gisela (Mrs. William Gresser) and Katherine Kahn; and a son, Julius Kahn, Jr.

Mr. Kahn was elected a Junior of the American Society of Civil Engineers on May 3, 1898; an Associate Member on October 3, 1900; and a Member on January 16, 1917.

WINFIELD SCOTT KING, M. Am. Soc. C. E.[1]

Died November 15, 1944

Winfield Scott King, the son of Jacob King and Christine (Christiansen) King, was born in Platte County, Nebraska, on January 19, 1862.

He attended high school in Omaha, Nebr. In 1883, at the age of twenty one, he was employed by the Oregon Short Line Railroad Company, directing surveys from Wyoming and Montana to Oregon. In 1889 he became chief engineer on the construction of the Omaha stockyards. Later he did similar work in St. Paul, Minn., Lincoln, Nebr., and Fort Worth, Tex. In 1910 he entered the paving construction business with headquarters in Omaha, and in 1915 he opened an office in Omaha as a consulting engineer.

Mr. King entered the United States Army in 1917, retiring with the rank of Captain in 1920. He then moved to Tucson, Ariz., where he continued to practice his profession. In 1921 he supervised a location survey for a railroad, connecting with the Southern Pacific Company's line in Arizona, which was seeking a port on the Gulf of California. Later he was associated with the city engineering office in Tucson. He retired from active practice in 1930.

On January 4, 1888, Mr. King was married to Margaret Catherine Hall. He is survived by two sons, Ralph H. King and Fred King, and two daughters, Margaret (Mrs. Oney Anderson) and Vera (Mrs. J. H. Thomas).

Mr. King was a man of determined character with a high regard for, and understanding of, his fellow men.

Mr. King was elected a Member of the American Society of Civil Engineers on December 6, 1899. He became a Life Member in January, 1932.

WALTER HAROLD KIRKBRIDE, M. Am. Soc. C. E.[1]

Died December 20, 1944

Walter Harold Kirkbride, the son of Charles Henry and Louise (Holloway) Kirkbride, was born in Pueblo, Colo., on January 22, 1874. He went to California at an early age. After attending grammar school and the College of the Pacific at Stockton, Calif., he entered Stanford University in Palo Alto, Calif., with the pioneer class of 1891. He was graduated with the degree of Bachelor of Science in Civil Engineering in 1895.

Mr. Kirkbride began his engineering career in 1895 as a United States deputy mineral surveyor, but in 1898 identified himself with railroad construction in the capacity of assistant chief engineer on location and construction for the Sierra Railway Company of California from Oakdale to Jamestown, Sonora, Tuolumne, and Angels Camp, Calif. From February, 1902, to August, 1902, he was chief of field party on a survey for the Shasta Mineral Belt Railway Company from Anderson to Alturas, Calif.

---

[1] Memoir prepared by John H. Gardiner, M. Am. Soc. C. E.

[1] Memoir prepared by C. R. Harding, M. Am. Soc. C. E.

He became associated with the Southern Pacific Company on August 13, 1902, as assistant engineer on the Sacramento Division in California, and later held the following engineering positions: From 1904 to 1906, roadmaster at Red Bluff, Calif.; from 1906 to 1909, assistant resident engineer, Sacramento Division; and, from 1909 to 1917, division engineer on Sacramento and Coast divisions and also assistant superintendent of the Sacramento Division with headquarters at Sacramento, Calif. In 1918 he was appointed chief engineer of the Pacific Lines, Southern Pacific Company, for the United States Railroad Administration, serving during World War I until March 1, 1920, when federal control of railroads ceased. After the railroads were returned to private ownership, Mr. Kirkbride was engineer, maintenance of way and structures, for the Southern Pacific Company. He held this position until 1932, when he was appointed chief engineer. Mr. Kirkbride was also chief engineer of the Northwestern Pacific Railroad Company and the San Diego and Arizona Eastern Railway Company, subsidiaries of the Southern Pacific Company.

As chief engineer of the Southern Pacific Company, Mr. Kirkbride supervised about 9,000 road miles of railroad in seven western states and participated in much of the railroad development that occurred in these states during the last forty years. Between 1918 and 1944 he supervised the expenditure of approximately $1,000,000,000 for maintenance of track, roadway, and structures, and for additions and betterments to railroad facilities.

Among the projects with which he was associated were the Redding to Delta (Calif.), 30.1-mile-long change of tracks, occasioned by the construction of Shasta Dam and reservoir for the Central Valley Project of the federal government; the Martinez-Benicia double-track railroad bridge across the Straits of Carquinez in California; the Los Angeles (Calif.) Union Passenger Terminal; the extensive railroad line change through San Jose, Calif.; railroad line relocations and reconstructions in Southern California after the 1938 floods; construction of the 400-ft span crossing the Colorado River at Yuma, Ariz., including the terminal yard tracks at Yuma and the relocation of the main line eastward of Yuma; and bridges over the Sacramento, American, San Joaquin, Los Angeles, Santa Ana, and other rivers.

After nearly forty-two years of service, Mr. Kirkbride, at the age of seventy, retired as chief engineer of the Southern Pacific Company on January 31, 1944. Because of his interest in, and knowledge of, civic affairs he was appointed by the Hon. Roger Dearborn Lapham, Mayor of San Francisco, as a member of the Board of Permit Appeals of that city. He held this office until his death at Dunsmuir, Calif., on December 20, 1944, after a brief illness.

Mr. Kirkbride was highly successful in stabilizing sinking roadbeds by applying the principles of soil mechanics. Notable among his accomplishments were the roadbeds on the Suisun marshes and Elkhorn slough in California, and on the Lucin cutoff across Great Salt Lake in Utah. He also introduced the principle of drain tunnels to correct sliding fills. In connection with the adaptation of hydraulics to river control, he personally developed certain types of jetties and other protective devices which resulted in the permanent protection of the railroad from flood erosion by rivers and by streams flowing in alluvial soil on steep gradients.

Mr. Kirkbride was consulted by the first group of engineers engaged to study the problem of the San Francisco (Calif.) Bay Bridge crossing; and, since the final construction plans for the San Francisco-Oakland Bay Bridge provided for the operation of the Southern Pacific electric lines, he took a prominent part in the studies relating to the terminals of the bridge and in the construction problems affecting the substructure. He was also on the committee appointed by the Hon. James Rolph, Jr., then Governor of California, to make a preliminary investigation of the Central Valley Project. This study culminated in the adoption of the site of the Shasta Dam and its ultimate construction.

During his years of railroading, Mr. Kirkbride was responsible for the development of many railroad devices, including the rail gage plate, of which he was sole inventor, adopted in 1930 and used as a standard on the Southern Pacific Lines to protect railroad ties from mechanical wear and to prevent spread track. He prepared numerous papers on engineering and construction subjects. He received the Thomas Fitch Rowland Prize from the Society in 1935 for his paper on "The Martinez-Benicia Bridge."[2] Mr. Kirkbride participated in the editing of "Marine Borers and Their Relation to Marine Construction on the Pacific Coast," in 1927[3] and "Termites and Termite Control," in 1934.[4] He was chairman of the standardization committee of the Southern Pacific Lines.

Mr. Kirkbride conceived the idea for the monument erected at the Sacramento railroad passenger station, in memory of Theodore Dehone Judah,[5] M. Am. Soc. C. E., the first chief engineer of the pioneer Central Pacific Railroad (later the Southern Pacific Lines). This memorial was dedicated on February 25, 1931, and a mural was placed in the Sacramento station showing the "Driving of the Last Spike." These tributes to Mr. Judah were financed by voluntary subscriptions from the personnel of the Southern Pacific Company.

A member of the American Railway Engineering Association in 1915, Mr. Kirkbride was director from 1925 to 1928, and served on the rail committee from 1933 to 1944. He also belonged to the American Wood-Preservers' Association (life member in December, 1944); the Engineers', Commercial, and Commonwealth clubs, all of San Francisco; the Pacific Railway Club (past-president); the California Historical Society; and the Seismological

Society of America (director from 1933 to 1944 and president when he died). He was a member of California Lodge No. I, Free and Accepted Masons, in San Francisco, and of Phi Kappa Psi fraternity. He was a Past-President and former Director of the San Francisco Section of the Society.

Recognized as one of the nation's foremost railroad engineers, Mr. Kirkbride was noted for his thorough knowledge of the engineering details encountered in daily activities, and for his earnestness and integrity of purpose and judgment in the solution of the many intricate problems which were his responsibility. Possessing a vigorous mentality and high moral courage, he could present his conclusions with forceful ability and usually convinced those who sought his counsel.

In 1902 he was married to Martha Sims of Nevada City, Calif. He is survived by his widow and a daughter, Audrey (Mrs. Harold Miles Tucker). Mr. Kirkbride had a pleasing personality and was modest and unassuming; he was a devoted husband and father—in short, he was a good American and no higher tribute can be paid to any man.

Mr. Kirkbride was elected a Member of the American Society of Civil Engineers on November 3, 1915. He would have become a Life Member in January, 1945.

FREDERIC ARNOLD KUMMER, M. Am. Soc. C. E.[1]

Died November 22, 1943

Through the death of Frederic Arnold Kummer the American Society of Civil Engineers lost one of its most individual and internationally known members. He was born in Catonsville (Baltimore), Md., on August 5, 1873. After receiving his preliminary education in the public schools and high schools of Baltimore, he was graduated from Rensselaer Polytechnic Institute at Troy, N. Y., in 1894.

Mr. Kummer was first employed, for more than a year, on the editorial staff of the *Railroad Gazette*. In 1896 he resigned to become salesman and engineer for the American Wood Preserving Company of Philadelphia, Pa. He remained with this company until 1898 designing and erecting small plants for the treatment of railroad ties and bridge timbers for various rail and railroad companies. He resigned in 1898 to accept employment as New York representative and later as general manager at Catskill, N. Y., for the Eastern Paving Brick Company. In this capacity, Mr. Kummer had direct charge of all the paving work and contracts for paving brick amounting to more than twelve million bricks per year, and also directed the extensive plant manufacturing of the company. Two improved permanent down-draft brick kilns of the largest size (five 100-ft brick chimneys) were designed by him and erected under his supervision. He also directed track construction in and around shale clay banks.

---

[1] Memoir prepared by Frederick Philip Stieff, Vice-Pres., Chas. M. Stieff, Inc., Baltimore, Md.

On June 6, 1900, Mr. Kummer presented a paper on "A Proposed Method for the Preservation of Timber,"[2] for which he won the Society's Collingwood Prize for Juniors in 1902.

In 1901 he was appointed general manager of the United States Wood Preserving Company of New York, N. Y. While with this company, he was in sole charge of constructing modern wood block pavements in most of the principal cities of the United States for streets, bridge floors, etc. This work included most of the main streets in lower New York, including Broadway, and many other paving contracts presenting unusual and novel features. He also directed the extensive plant producing the paving material. The projects under Mr. Kummer's supervision exceeded a quarter of a million square yards of pavement a year—a substantial amount for those days.

In spite of the meticulous exactitude required of an engineer, beneath the surface of Frederic Arnold Kummer there lay a definite tendency toward the artistic, the creative. He had casually toyed with painting in oils and was finally importuned by his artistic friends to show his work at one of the better annual exhibitions. In 1903 he sent a canvas, "A Summer Sea," to the Seventy-Second Annual Exhibition of the Pennsylvania Academy of Fine Arts. It was accepted and hung with canvases of Whistler, Sargent, Homer, Oakley, Innes, Borglum, Sloan, Henri, and other first ranking contemporary artists.

Mr. Kummer also continued his literary career. On November 21, 1906, he read a treatise on "The Development of Wood Block Pavements in the United States" before the Boston Society of Civil Engineers.[3]

In 1907 Mr. Kummer and his second wife traveled extensively in Europe, presumably in the interests of his profession. However, he saw and absorbed far more than engineering data. Later this was to serve him well. At this juncture in his life a holocaust occurred which caused a complete metamorphosis of his entire career, for, on his return to the United States, he found that the firm by which he had been retained had ceased to exist. As a result, Mr. Kummer had to pause to consider his next step carefully—as to what business or other career offered an advantageous future. His pen had upheld his engineering development well from the start, and his imagination had fed both his pen and his profession. Thus, it was that Frederic Arnold Kummer decided to write. He contributed short stories to the old *Smart Set, Blue Book, Red Book, Ainslee's,* and many other of the most popular current periodicals.

His was a unique case. Many authors, or followers of the arts, have begun their careers in distasteful employment, either through misguidance or duress, and only later have they been freed from uncongenial oppression to follow their literary bents. For example, Sir Arthur Conan Doyle had been a doctor; Rimski-Korsakov was trained as an officer in the Russian Navy. Unlike these men, Mr. Kummer had shown definite qualifications as an established engineer, pointing to future and greater successes in that profession.

---

[2] *Transactions*, Am. Soc. C. E., Vol. XLIV (December, 1900), p. 181.

[3] "The Development of Wood Block Pavements in the United States," by Frederic A. Kummer, *Journal*, Assn. of Eng. Societies, November, 1906.

The accuracy of his intuition was evidenced by the immediate and continued success of his short stories. This was responsible in 1910 for his first play, "Mr. Buttles," which was developed from a novelette and starred Henry Dixey, then a well-known actor. In Mr. Kummer's first year as a playwright, he wrote his second play, "The Other Woman," starring Blanche Walsh. Then there fairly burst forth from his versatile pen, books of verse (blank and otherwise), novels, detective stories, histories, sophisticated satire, juvenile books for musical comedies, a libretto for an opera, plays, movies, etc. He was the most prolific and versatile literary personality Baltimore has produced with the exception of Edgar Allan Poe. Among his works are:

1911: "The Green God," a novel.

1912: "The Brute" and "The Diamond Necklace," both novels also produced as plays; and, under the nom de plume of Arnold Fredericks, "One Million Francs," a novel, and "The Ivory Snuff Box" (first a serial, then a novel, later a motion picture, and finally a book translated into Braille).

1913: "The Second Sixpence," a novel, and "The Painted Woman," a drama (produced in Baltimore and New York, starring Florence Reed).

1914: "A Lost Paradise," a novel, and "Many Happy Returns" (a production of the Paint and Powder Club of Baltimore).

1915: "The Blue Lights" and "The Little Fortune," both novels under the name of Arnold Fredericks; and "The Second Coming," a novel written in collaboration with Harry Pratt Janes.

1916: "The Slave Market" (a new version of "The Painted Woman" produced as a motion picture by Jesse Lasky with Pauline Fredericks in the leading rôle; in 1917 this play was also published as a novel).

1917: "The Film of Fear," a novel under the name of Arnold Fredericks.

1919: "The Battle of Nations," a children's history of World War I (published in both England and Canada); two novels, "The Web" and "Peggy-Elsie" (in collaboration with Mary Christian); and two musical comedies, "The Magic Melody," with music by Sigmund Romberg, and "My Golden Girl," with music by Victor Herbert.

1920: "The Bonehead," a play.

1921: "The Pipes of Yesterday," in collaboration with Mary Christian, and "Plaster Saints," both novels.

1922: "The First Days of Man," the first volume of "The Earth's Story." (This series was later translated into German, Norwegian, Swedish, and Danish.)

1923: "The First Days of Knowledge," the second volume of "The Earth's Story," and "The Voice," a play.

1924: "The First Days of History," the third volume of "The Earth's Story," and "Phryne," a drama in blank verse.

1925: "The Road to Fortune," a novel.

1927: "Love's Greatest Mistake," a novel.

1928: "Ladies in Hades," a sophisticated satire.

1929: "Maypoles and Morals," a satire; and, as Arnold Fredericks, "The Mark of the Rat."

1930: "Gentlemen in Hades," a satire.

1931: "Forbidden Wine," a novel.

1932: "The Golden Piper," a novel.

1933: "Red Clay," a novel; and, under the pseudonym of Arnold Fredericks, "The Spanish Lady," also a novel.

1934: "Manhattan Masquerade," a detective story.

1935: "The Captive," a grand opera ("The Painted Woman") with music by Gustav Strube, first conductor of the Baltimore Symphony Orchestra, successfully produced in Baltimore.

1936: "Design for Murder," a detective story.

1937: "Death at Eight Balls," a detective story.

1938: "The Scarecrow Murders" and "The Twisted Face," both detective stories; and "The Great Road," a child's book.

1939: "Leif Erikson the Lucky," an historical story for adolescents.

1940: "Courage Over the Andes," another juvenile novel.

1941: "Torch of Liberty," his last book for children.

1943: "Perilous Island," a novel.

In 1941 Mr. Kummer's health began to fail. Although for long periods he was confined to his bed, his keen and alert mentality and indefatigable courage never failed him. He never "merely wrote." His works were sponsored by the leading publishers of his day, and during his final ailing years "The Great Road," "Leif Erikson the Lucky," and "Courage Over the Andes" were chosen by the Juvenile Book of the Month Club. The meticulousness his engineering training had bred in Mr. Kummer never permitted him to compromise with true merit. His last books maintained the standard from which he had never deviated during his entire literary career.

"Perilous Island," staged in the Aleutians, written just before his death was his last published novel and an extremely successful one. Posthumously, his serial "Michael Blake and the Minotaur" appeared in *Boys' Life*, the monthly magazine of the Boy Scouts of America.

During his lifetime, Mr. Kummer also continued his art career and painted numerous pictures, among them "The Yellow Pawn," "Motherhood," and "The Belgian."

"Fritz" Kummer, as he was affectionately known to his intimates, was a definite personality. He had a most alert and agreeable mentality. His letters to the discussion columns of the daily press covered fields ranging from the Spanish Revolution to the pay of local school teachers. Vitally interested in all paramount problems of the day, he followed the progress of the world and of the war via radio with utmost fidelity.

In 1894 Mr. Kummer was married to Clare Redmond Beecher, later to become known as the playwright Clare Kummer. A daughter, Marjorie Beecher Kummer, was married to Roland Young, the stage and screen actor. A second daughter, Frederica, died in infancy. His first marriage ended in divorce, and he was married for the second time in 1907 to Marion J. McLean. By his second marriage he had three children, Marion McLean (Mrs. Ernest E. Wachsmuth), Frederic A., Jr., and Joseph T. T. Mr. Kummer was essentially a man who lived with, and for, his family. Always interested in aspirants for literary achievement, he was ever willing to help with advice and counsel and proved a valuable literary "father confessor" to many. His counsel was, however, honest and sincere and not for those who preferred praise to improvement. Consequently his advice was desired and esteemed.

Frederic Arnold Kummer was a member of the Society of American Dramatists and Composers, The Authors League of America, and Chi Phi fraternity. He belonged to the Paint and Powder Club of Baltimore. This unique organization has been in existence for more than a half century. An amateur theatrical club, until recently of stag membership, during the years of its existence, it has operated only in behalf of charity and contributed to charitable organizations more than a hundred thousand dollars. Among its members are such nationally known personalities as Harry Lehr and Baldwin Sloan, the latter being the only Baltimorean except Mr. Kummer who had three plays playing on Broadway simultaneously. In 1922 Mr. Kummer was elected president of the club and that year sponsored a most successful revival of "The Runaway Girl."

Baltimore lost an outstanding personality on the death of engineer-author-playwright-artist Kummer; the Society, a most highly esteemed member; and the world at large, an able and respected historian, a successful playwright, and a teller of tales of deservedly international popularity.

Mr. Kummer was elected a Junior of the American Society of Civil Engineers on April 30, 1895; an Associate Member on March 4, 1903; and a Member on October 2, 1906.

EDWARD ROWLAND LEWIS, M. Am. Soc. C. E.[1]

DIED AUGUST 13, 1944

Edward Rowland Lewis, the son of David Mynard and Mary (Rowland) Lewis, was born in Raritan, N. J., on November 20, 1869. His father was a civil engineer who practiced in New York, N. Y., and later moved to New Jersey, where he became interested in railroad contracting. This business took him to various states in the Middle West and his family followed him. Young Edward's primary education and high school education were received in the public schools of Champaign, Ill. In 1885 he entered the University of Illinois at Urbana, remaining for one year.

In the summer of 1886, the family removed to Atlantic, Iowa; and in September, 1886, Edward Lewis entered the University of Iowa, at Iowa City, from which he was graduated in 1890 with the degree of Bachelor of Science in Civil Engineering. In 1906 he received the degree of Civil Engineer from this same institution.

---

[1] Memoir prepared by J. E. Bebb, Assoc. M. Am. Soc. C. E.

During his summer vacations while at the University, he worked for the Missouri Pacific Railroad Company as an axman, rodman, and clerk on location. After graduation, he served as assistant engineer of construction for the Omaha Southern Railway. In June, 1892, he went to Sheridan, Wyo., where he engaged in private practice, specializing in survey and irrigation work. He compiled a map of the City of Sheridan and laid out many of the streets, sewers, and other municipal works. In May, 1896, he accepted a position as division engineer, Mississippi River Improvements, for the U. S. Government, on levee location and construction, soundings, and mapping.

He did not, however, remain long in government employ. Early in 1899 Mr. Lewis went to England and then to South Africa where he worked for a short time for the Electric Tramways Company of Cape Town. Later he became associated with the British Cape Government Railways as assistant engineer on location and construction of government-owned railway lines, including the design and construction of bridges, buildings, water service, and other railroad facilities. This work extended from Cape Colony well into equatorial Africa.

Since the Boer War, which began in 1899, caused a cessation of railroad construction, Mr. Lewis returned to the United States in 1901. He accepted a position as engineer of construction for the White River Railroad (later a part of the Missouri Pacific Railroad Company) at Batesville, Ark., and later was appointed division engineer of the Fort Smith and Western Railroad. In the fall of 1902, he returned to South Africa and resumed his connection with the Cape Government Railways, as locating engineer and district engineer at Port Elizabeth and Mafeking.

In the early winter of 1905, he returned to the United States and became assistant engineer on the Keweenaw Central Railroad Company (later part of the Copper Range Railroad Company). In August, 1906, he was appointed division engineer, Michigan Central Railroad Company, with headquarters at Bay City, Mich. He held this position until June, 1912, when he became assistant to the general manager for the Duluth, South Shore and Atlantic Railway Company at Duluth, Minn., in charge of an extensive program of bridge and building renewals. In 1918, he was appointed chief engineer of the Duluth, South Shore and Atlantic Railway Company, with headquarters, as before, at Duluth.

Mr. Lewis was keenly interested in technical journalism and had contributed many articles to the technical press. He was the author of a volume entitled "Winter Track Work."[2] Thus, it was an entirely logical decision on his part when, in March, 1919, he accepted a position on the editorial staff of the Simmons-Boardman Publishing Corporation of Philadelphia, Pa., publishers of *Railway Age* and *Railway Engineering and Maintenance.* He became managing editor of the "Maintenance of Way Cyclopedia"[3]—a monumental work embodying all phases of railway design, construction, and maintenance. This volume was completed early in 1921 and in March, 1921, Mr. Lewis was appointed office engineer of the Michigan Central Railroad Company with offices at Detroit, Mich. In January, 1924, he was appointed principal assistant engineer and served in that capacity until June, 1933, when he resumed his former position as office engineer. He retired on December 1, 1939.

---

[2] "Winter Track Work," by E. R. Lewis, Ry. Educational Press, Inc., Chicago, Ill., 1917.

[3] "Maintenance of Way Cyclopedia," edited by E. T. Howson and others in cooperation with the A.R.E.A., Simmons-Boardman Pub. Corp., New York, N. Y., 1921.

After his retirement, Mr. Lewis made his home at St. Petersburg, Fla., but spent the summer months each year in the north. He died at St. Petersburg on Sunday, August 13, 1944.

In June, 1901, Mr. Lewis was married to Madeline Young, of La Crosse, Wis., who survives him. They had no children. He was a member of the Presbyterian Church.

Among railroad engineers, Mr. Lewis was recognized as an authority on track construction and maintenance, and his associates knew him as a kindly gentleman and a loyal friend. His long experience and world-wide travel gave him a fund of knowledge from which, when the spirit moved him, he delighted to draw and regale his friends. He was a raconteur of no mean ability. His loss will be keenly felt.

In 1906 he became a member of the American Railway Engineering Association and served for many years on various important committees. He was chairman for three years of the committees on railway labor. He also belonged to the Detroit Engineering Society and the Detroit Economic Club.

Mr. Lewis was elected a Member of the American Society of Civil Engineers on May 17, 1913.

FREDERICK CHARLES LOHMANN, M. Am. Soc. C. E.[1]

Died January 1, 1944

Frederick Charles Lohmann was born in Gibson City, Ill., on October 26, 1884, the son of Louis Henry and Etta (Harnack) Lohmann.

After completing his secondary and high school studies in Gibson City, Mr. Lohmann entered the University of Illinois, at Urbana, from which he was graduated in 1911 with the degree of Bachelor of Science in Civil Engineering.

Immediately after graduation, Mr. Lohmann became an inspector on the construction of the high school in Gibson City. In November, 1911, Mr. Lohmann was appointed assistant city engineer of Champaign, Ill., and, in May, 1915, he became city engineer of Champaign. From 1927 to 1931, Mr. Lohmann was superintendent of building construction for the University of Illinois.

In 1931 he again became city engineer of Champaign, continuing in this capacity until 1935. From 1935 to 1939 he served as director for the Works Progress Administration in Champaign County. From 1939 until his death, Mr. Lohmann was employed by the U. S. Army Engineers. His first work with the Army Engineers was the rebuilding and enlarging of Chanute Field,

---

[1] Memoir prepared by Wallace M. Lansford, M. Am. Soc. C. E.

Ill. Later he was transferred to the Columbus (Ohio) Office of this department.

On June, 5, 1915, he was married to Ada L. Kennedy of Brookston, Ind. Mrs. Lohmann died in April, 1943, after an illness of more than eight years. Mr. Lohmann is survived by two sisters, Emma (Mrs. L. F. Whallon) and Laura; and a brother, Lawrence.

Mr. Lohmann belonged to the First Presbyterian Church of Champaign and the Masonic Fraternity, Western Star Lodge of Champaign. He was a member of the Western Society of Engineers, the Illinois Society of Engineers, Inc. (past-president), and the Central Illinois Section of the American Society of Civil Engineers (past-president).

He was honored and respected by his many friends for his sterling character and for his professional loyalty, honesty, and perseverance.

Mr. Lohmann was elected a Member of the American Society of Civil Engineers on January 15, 1923.

MOSES JEROME LOOK, M. Am. Soc. C. E.[1]

DIED JULY 11, 1944

Moses Jerome Look, the son of Warren Jerome and Delphina (Look) Look, was born at Addison, Me., on February 24, 1869. He attended the grammar and high schools of Boston, Mass., and studied civil engineering at Massachusetts Institute of Technology in Boston.

After graduation in 1892, Mr. Look was in charge of a field party on various engineering projects for E. A. W. Hammatt,[2] M. Am. Soc. C. E. In August, 1893, he entered the field of water supply engineering in which he was destined to continue for the remainder of his life. At that time the Massachusetts State Board of Health, of which Frederic P. Stearns,[3] Past-President, Am. Soc. C. E., was chief engineer, was just beginning surveys and investigations for a metropolitan water supply, and Mr. Look became transitman on one of the survey parties which operated in the vicinity of West Boylston and Clinton, Mass., in an area which was later to become the site of the Wachusett reservoir. He served in this position until February, 1895, and then was briefly engaged on the construction of Payson Park reservoir for the City of Cambridge (Mass.) and on surveys for improvement of the Neponset River.

When the Metropolitan Water Board was established in December, 1895, an engineering force was organized on which, until 1905, Mr. Look served as assistant engineer and division engineer for the Wachusett reservoir on surveys, studies, plans, and construction, including work on north and south dikes and the location and construction of the Central Massachusetts Railway and of several miles of highways made necessary by the building of the reservoir.

---

[1] Memoir prepared by George W. Booth, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 92 (1928), p. 1698.

[3] For memoir, *ibid.*, Vol. LXXXIII (1919–1920), p. 2132.

MacArthur Brothers and Winston and Company was the contractor for the main Wachusett dam and certain related works. The energy and executive talents of the young engineer were so impressive that, in 1905 upon completion of the Wachusett work, this firm employed Mr. Look as engineer and general superintendent. From 1917 until 1930 he remained with MacArthur Brothers and Winston and Company in the same position and as vice-president and manager for Winston and Company.

During these twenty-five years Mr. Look was engaged on the following construction contracts, most of them of outstanding importance and many involving difficult problems: Cross River dam and reservoir at Katonah, N. Y., for the City of New York, N. Y.; Ashokan dam and dikes and the Catskill headworks; a dam and a reservoir for Pittsfield, Mass.; shipbuilding at Kingston, N. Y., and West Point, Va.; Camp Abraham Eustis and a balloon school in Virginia; Skiff Creek dam and reservoir for Newport News, Va.; Scituate dam, dikes, and purification works for Providence, R. I.; Cooper Lake dam and reservoir, Kingston, N. Y.; Cobble Mountain dam and reservoir, Springfield, Mass.; and Alcove dam, Albany, N. Y. During this period Mr. Look conducted numerous investigations and made reports and estimates for bids on various water supply and railroad projects.

In 1930, having already had experience as consultant and expert engineering witness, Mr. Look established his office as a consulting engineer, practicing for the remainder of his life in that field. He was engaged in numerous instances by New York City, Springfield and Fitchburg, Mass., and the Commonwealth of Massachusetts.

Mr. Look was married in 1893 to Cora Groves. Mrs. Look died in 1895. In 1900 he was married to Amy G. Wood. He is survived by his widow; a son by his first marriage, Frederick W. Look; and two daughters by his second marriage, Laura (Mrs. Galland Frank) and Miriam (Mrs. Donald B. MacMillan).

The fact that Mr. Look was so successful was evidence of his versatility, his fine character, and good judgment. He possessed tremendous energy and was never content to be idle. Insight into a man's real life can often be obtained by observation of his off-hour activities, his hobbies, and his so-called play. Born of a seafaring family on one of the finest seacoasts in the world—that of Maine—naturally Mr. Look was a lover of the sea, and all that pertains to it. From the door of his summer home in Casco Bay he could see Eagle Island and the cottage of Robert E. Peary, Admiral, U. S. Navy. Mr. Look's interest in northern adventure and arctic exploration was such that he was elected president of the MacMillan Arctic Association year after year.

When Donald B. MacMillan, Commander, U. S. Navy, and his seven men were marooned for four years far up on the northern shores of Greenland, Mr. Look was the first to contribute toward their relief which was accomplished successfully in 1917 after repeated failures.

Commander MacMillan, through his intimate associations with Mr. Look when "off the job," knew him as few men did, and paid him the following tribute:

"We are all the better for his having lived and his influence will be with us always, as he will be. When a man lives on in the hearts of those who love and have loved him, then he has fulfilled his mission in life. Praise and honors and standing in the community are nothing in comparison to this. The rank of any man is his power to uplift others, contribute something in the altogether too short time allotted us. One is indeed fortunate if he happens to be blessed with that power, and Jerry had it."

Mr. Look was a member of the Society of American Military Engineers, the New England Water Works Association, the Museum of Natural History, the Boston City Club, the Alumni Association of Massachusetts Institute of Technology, and the Boylston Lodge, A. F. and A. M., of which he was Master in 1900. He was licensed as a professional engineer in the states of Massachusetts and New York.

Mr. Look was elected an Associate Member of the American Society of Civil Engineers on May 6, 1903, and a Member on April 4, 1905. He became a Life Member in 1938.

JOHN HERBERT McMANUS, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 6, 1941

John Herbert McManus, former chief of the Bureau of Claims of the Board of Water Supply, of the City of New York, N. Y., died on September 6, 1941, at Orthmann Sanitarium, in Kingston, N. Y., following a long illness. He had retired on February 28, 1941, because of ill health, after almost thirty-five years of continuous service with the Board of Water Supply.

Mr. McManus was born in Boston, Mass., on July 9, 1882, the son of Charles Aloysius and Agnes (Kidney) McManus. He received his early education in that city, and studied sanitary and civil engineering at the Massachusetts Institute of Technology, in Boston, from which he was graduated in June, 1905, with the degree of Bachelor of Science. He then taught at the Institute for one year as assistant instructor in civil engineering.

On June 13, 1906, Mr. McManus reported to the Board of Water Supply of the City of New York and was assigned to the Reservoir Department at Brown Station, New York. For the next seven years he was engaged on construction work in the Ashokan Reservoir area, first in the West Hurley section, then at the Olive Bridge Dam during the most important stages of the work there, and later at the headworks of the Catskill aqueduct where he helped to build a section of the aqueduct, along which was located the then largest venturi meter in the world. He assisted in the construction of the Ashokan screen chamber and lower gate chamber, the waste channel and reinforced concrete bridge spanning it, and the aerator. In addition, he did considerable incidental work on superstructures, roads, landscaping, and several reinforced concrete bridges.

---

[1] Memoir prepared by Edward P. Ward, Asst. Engr., Board of Water Supply, and James A. Guttridge, M. Am. Soc. C. E.

While on construction work, Mr. McManus aided considerably in the preparation for trial of various claims against the city, and as result was assigned to the Board's Bureau of Claims in 1913 to record, classify, investigate, and report upon claims of all kinds filed in connection with the construction of the water works and to assist the city's Law Department at the trial of such claims. Early in 1919 he was appointed chief of the Bureau and continued in this capacity until his retirement. While Mr. McManus was chief of the Bureau, his judgment was frequently utilized for important determinations of policy in the matter of the disposition of claims brought for all sorts of damages by persons whose properties were involved in the condemnations necsary for the great work with which Mr. McManus was identified.

Although he had no formal legal training, his familiarity with the many and complicated leading cases which serve as precedents in condemnation proceedings made Mr. McManus invaluable to the legal staff. This litigation frequently involved engineering problems and concepts with which even outstanding members of the legal profession could be expected to have little acquaintance. His early experience as instructor aided Mr. McManus in imparting to his legal associates sufficient technical data to enable them to explain many things in understandable terms to commissions and courts, not ordinarily familiar with engineering methods.

His wide acquaintance with leading members of his own profession contributed in no small measure to his fund of versatile information, so essential in his highly specialized activities. Naturally of a studious nature, Mr. McManus possessed a more comprehensive and detailed knowledge of the New York City water supply system than many engineers engaged in the construction of its component parts.

With his associates, including those under his personal direction, he always was considerate, making their problems his own and considering it his obligation not only to work zealously for the interests of the City of New York, but to assist in the advancement of other employees. His loyalty exemplified the universally recognized high morale of the Board of Water Supply.

Of modest and unobtrusive personality, Mr. McManus directed, without display or ostentation, but with efficiency, dispatch, and completeness to the last detail, the varied activities of the Bureau of Claims.

A great lover of the outdoors, his recreational activities included baseball, tennis, and hockey, and during his later years he was also interested in skating, skiing, hiking, and golfing. There were few of the highest peaks of the Catskills upon which he had not walked or camped. His favorite study was geology, with which he was unusually familiar, and he keenly enjoyed discovery and identification of specimens in the field.

A licensed professional engineer in the State of New York, Mr. McManus was also a member of the New England Water Works Association.

Surviving are his widow, the former Mary F. Cusack, to whom he was married on September 10, 1913; three sons, John H. McManus, Jr., Thomas C.

McManus, and Edwin C. McManus; a daughter, Mary C. McManus; and a brother, Charles A. McManus.

Mr. McManus was elected a Member of the American Society of Civil Engineers on October 1, 1928.

DAVID WHITE McNAUGHER, M. Am. Soc. C. E.[1]

Died November 24, 1943

David White McNaugher, the son of Joseph and Jessie (White) McNaugher, was born in Allegheny (later Pittsburgh), Pa., on November 23, 1859. He attended public schools and Newell Institute in Pittsburgh until 1878, when he entered Westminster College at New Wilmington, Pa., as a sophomore, being graduated in 1881 with the degree of Bachelor of Arts. The following fall he entered the freshman class at Rensselaer Polytechnic Institute in Troy, N. Y., from which he was graduated in 1885 with the degree of Civil Engineer.

During vacations from Rensselaer Polytechnic Institute, Mr. McNaugher worked in the engineering office of James P. Witherow and also took a special course in chemistry. During the summer after graduation from the Institute, he was again engaged by Mr. Witherow. In the fall of 1885 he entered the employ of the Troy Steel and Iron Company (of which the late Robert W. Hunt,[2] M. Am. Soc. C. E., was general superintendent) as assistant chemist and also as an assistant in the engineering corps in charge of the reconstruction of the steel plant.

When Captain Hunt left the Troy Steel and Iron Company and opened the Bureau of Inspection, Tests and Consultation at Chicago, Ill., Mr. McNaugher went with him and took charge of the laboratory and also the inspection of rails and other materials. Later he was sent to Pittsburgh to supervise inspection at the Duquesne Steel Works.

In 1889 Mr. McNaugher joined the engineering and inspection firm of G. W. G. Ferris and Company of Pittsburgh, the partners being G. W. G. Ferris, James C. Hallsted, M. Am. Soc. C. E., W. F. Gronau, and Mr. McNaugher. This company designed the Ferris Wheel, of Chicago Exposition fame, in 1893. In the design and fabrication of the wheel many problems had to be solved which were new at that time. In 1894 Mr. Gronau withdrew from the firm and two years later Mr. Ferris died. The title of the firm was then changed to that of Hallsted and McNaugher. The company continued until 1900, when it was merged with the Robert W. Hunt Company, of Chicago. Mr. McNaugher had charge of the Pittsburgh office and became vice-president and treasurer of the Robert W. Hunt Company.

---

[1] Memoir prepared by C. G. Dunnells, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXVII (1924), p. 1360.

Mr. McNaugher belonged to the American Institute of Mining Engineers, Engineers' Society of Western Pennsylvania, American Railway Engineering Association, and American Society for Testing Materials.

He was a director of the Monongahela National Bank of Pittsburgh, a trustee of the Dollar Savings Bank of Pittsburgh, a trustee and the treasurer of Westminster College, a trustee of the Western Pennsylvania School for the Deaf, and president of the Board of Corporators of the Union Dale Cemetery of Pittsburgh. He was a member of the Duquesne Club of Pittsburgh and the Engineers Club of New York, N. Y. He belonged to the Fourth United Presbyterian Church of Allegheny, was a member of the Session, and was always active in its welfare and financial support.

On November 22, 1900, Mr. McNaugher was married to Josephine Scott, of Allegheny, who died on December 9, 1939. He is survived by two sons, David White McNaugher, Jr., and Robert Scott McNaugher, both graduates of Rensselaer Polytechnic Institute.

Mr. McNaugher was elected a Member of the American Society of Civil Engineers on June 3, 1908.

CHARLES STERLING MILLARD, M. Am. Soc. C. E.[1]

Died June 5, 1942

Charles Sterling Millard was born in Louisville, Ky., on May 3, 1874. He was descended from French and English stock. His father, formerly in the iron business in Utica, N. Y., moved to Indianapolis, Ind., and organized a railroad car building company. His maternal grandfather, Elisha Morgan Gilbert, was one of the organizers and first president of the Michigan Central Railroad Company.

As a boy Mr. Millard was educated in Clinton, Conn.; Lawrenceville Academy in Lawrenceville, N. J.; and the Holbrook School in Ossining, N. Y. After a year at Union College in Schenectady, N. Y., he entered the Sheffield Scientific School of Yale University in New Haven, Conn., where he taught for a short period after being graduated in 1896.

Returning to Indianapolis, he entered the maintenance of way department of the Pennsylvania Railroad Company. Next, he worked for the Peoria and Eastern Railway Company. In 1898, after brief service in the Spanish-American War, he returned to railroading as assistant engineer, maintenance of way, for the Peoria and Eastern Railway Company and soon was promoted to engineer, maintenance of way. In 1901 he became division engineer for the Delaware, Lackawanna and Western Railroad Company. Later he served for short periods as engineer, maintenance of way, for the Peoria and Pekin Union Railway Company, and as assistant engineer of construction for the Illinois Central Railroad Company.

---

[1] Memoir prepared by C. O. Sherrill and F. F. McMinn, Members, Am. Soc. C. E.

In 1903 he returned to the Peoria and Eastern Railway Company as engineer, maintenance of way, and three years later was promoted to engineer, maintenance of way, for the Cleveland, Cincinnati, Chicago and St. Louis Railway Company (Big Four). In 1910 he was made engineer of track and roadway and two years later was promoted to division superintendent of the Big Four. In 1914 he was returned to the Peoria and Eastern Railway Company where he was division superintendent for two years. In 1916 he was transferred to the Big Four as division superintendent. In 1918 he was appointed assistant general superintendent; and, in 1924, general manager of the Big Four, with headquarters at Cincinnati, Ohio. In 1930 he was appointed vice-president of the New York Central Railroad Company.

Aside from routine railroad operation, Mr. Millard was, perhaps, best known for his advanced principles in negotiation of labor relations. In addition to writing many of the rules governing labor relations on the Big Four, he was chosen independent arbitrator in a number of labor disputes. He was an active representative of the New York Central Railroad Company on the construction of the Cincinnati Union Terminal and served two terms as president and four as chief operating officer.

Interested in golf, during his middle age Mr. Millard helped to organize the Indianapolis Country Club. He also was a cabinet maker. During two summer vacations, when a boy, he was apprenticed in the pattern making shop of his father's car building company. Throughout his life this hobby provided him with tremendous interest and enjoyment.

Mr. Millard was director of ten corporations, principally subsidiaries of the New York Central Railroad Company. When he was elected an Associate Member of the Society in 1901, he was the youngest man to achieve this honor in the Society's history. He also belonged to many railroad associations.

On June 5, 1942, he died of coronary occlusion in Holmes Hospital in Cincinnati. He is survived by his widow, Elizabeth Ekin Millard; two sons, Charles S. Millard, Jr., U. S. Navy, and William E. Millard; a daughter, Mrs. Henry Lyman Greer; and four grandchildren.

Mr. Millard was elected a Junior of the American Society of Civil Engineers on May 2, 1899; an Associate Member on June 5, 1901; and a Member on January 31, 1905. He became a Life Member in 1936.

EGBERT JESSUP MOORE, M. Am. Soc. C. E.[1]

Died February 1, 1944

Egbert Jessup Moore was born on July 10, 1877, at Cutchogue, L. I., N. Y., the son of Isaac T. Moore and Susan (Jessup) Moore. He was educated in the schools of Middletown, N. Y., being graduated from the local high school in

---

[1] Memoir prepared by J. P. H. Perry, M. Am. Soc. C. E.

1895. He then entered Cornell University at Ithaca, N. Y., and was graduated with the degree of Civil Engineer in 1899.

After his graduation from Cornell Mr. Moore worked in the field and on steel erection for the Berlin Iron and Bridge Company until August, 1900. From September, 1900, to December, 1902, he served in the drafting rooms of the American Bridge Company at East Berlin, Conn., Buffalo, N. Y., and Philadelphia, Pa. He was a draftsman for the Phoenix Iron Company at Phoenixville, Pa., from December, 1902, to April, 1904. From April, 1904, until March, 1905, he was with S. Pearson Sons Company, contractors on the construction of the East River (New York, N. Y.) tunnels for the Pennsylvania Railroad Company. During these six years after his graduation from Cornell, Egbert Moore clearly showed the talents which later became outstanding in his life—that is, he demonstrated to his superiors his willingness to accept responsibility, his great capacity for hard work, and his dependability in all things. His unusually penetrating mind and his solid substantial character based on upright living which was to guide the remainder of his life also became evident.

In March, 1905, Mr. Moore entered the employ of the Turner Construction Company as engineer. The Turner Construction Company at that time was a small concern engaged in building construction, doing less than half a million dollars worth of work a year. This company specialized in reinforced concrete, then in its infancy as far as commercial usage went. Since there was little precedent for engineering design of buildings constructed of this material, originality, research, and experimentation were required.

From 1907 to 1918 Mr. Moore was chief engineer of the Turner Construction Company. In 1917 he became vice-president and a director. He retired from active duty on June 1, 1931, but continued as a director until his death, serving in that capacity for nearly twenty-seven years. He was a vice-president of the company through 1942.

During the thirty-nine years that Mr. Moore was connected with the Turner Construction Company he not only saw but played an important part in its expansion from a concern doing $442,000 worth of business yearly to one doing $93,000,000 worth of business yearly.

From the day Mr. Moore joined the Turner Company forces until the beginning of World War I he took a leading part in the development of sound design of reinforced concrete as a building structural material. He served as a member of the famous "Joint Committee" (representing various engineering organizations including, in addition to the Society, American Society for Testing Materials, American Concrete Institute, and Railway Engineering Maintenance of Way Association) which, after several years of arduous and sometimes controversial service, established principles for the design of reinforced concrete, particularly for spiral columns and flat slab floor construction, as well as for the more usual beam and girder floor system. Mr. Moore's contribution to the work of this committee was accepted throughout the engineering profession as outstanding.

While Mr. Moore was chief engineer of the Turner Company he directed its drafting rooms in preparing working details, shop drawings, and often fundamental designs for the 389 reinforced concrete buildings which the company was constructing.

During World War I, Mr. Moore was responsible for all problems of the company's personnel in regard to military service. He also selected men for the company's office and field forces, during the period when the company expanded from a $6,639,000 concern in 1916 to a $35,226,000 concern in 1918. After becoming vice-president, Mr. Moore for many years continued to function as the de facto chief engineer of the company. About 1923 he became an operating officer. Until his retirement in 1931 he fulfilled his duties most successfully.

After retiring from active participation in the management of the Turner Construction Company, Mr. Moore was promptly elected a member of the Board of Trustees of the Yonkers (N. Y.) Savings Bank and, when the United States entered World War II, he became chairman of Selective Service Draft Board No. 732 in Yonkers. Mr. Moore was a member of the Cornell Society of Civil Engineers, Cornell Club of New York, and the Hudson River Country Club.

On September 2, 1903, Mr. Moore was married to Georgia Holley. Their son, Clifford Moore, died in 1925 during his junior year at Cornell University. Mrs. Moore; a daughter, Sylvia (Mrs. James C. Freer); and a sister, Mrs. Herbert Woodhull, survive him.

A member of the Board of Trustees of the First Presbyterian Church of Yonkers for many years and chairman of that board for the past five years, Mr. Moore took an active part in the social and religious life of Yonkers. He was always a friend to young people and helped several girls and boys to obtain a higher education. His hobby was gardening. He was most interested in buying tiny evergreen trees by the hundred and watching them grow. When they became sizable trees, he gave them to friends and neighbors.

Mr. Moore was elected a Junior of the American Society of Civil Engineers on March 31, 1903; an Associate Member on February 7, 1906; and a Member on May 31, 1910.

JOHN PATRICK MYRON, M. Am. Soc. C. E.[1]

DIED MARCH 21, 1944

John Patrick Myron was born at Peninsula, Summit County, Ohio, on September 7, 1880, the son of Michael Myron and Margaret (Mourn) Myron.

Mr. Myron was educated in the grade and high schools of Peninsula. At the age of eighteen, being unable to continue his education, he moved to Pittsburgh, Pa., where there were greater opportunities for engineering experience.

---

[1] Memoir prepared by F. O. Leopold, President, F. B. Leopold Co., Inc., Pittsburgh, Pa.

In November, 1898, shortly after his arrival in Pittsburgh, he secured a position as timekeeper in charge of labor on construction work with the Jones and Laughlin Steel Company where he remained until March, 1902. Being determined to satisfy his desire for further technical training, he enrolled with the International Correspondence Schools studying civil and bridge engineering at night. After arduous work and study, he received a certificate as bridge engineer from the International Correspondence Schools in 1907.

Not being satisfied as timekeeper with his technical knowledge, he left the Jones and Laughlin Steel Company, and in March, 1902, secured a position with the Fisher Foundry and Machine Company of Pittsburgh, as designing draftsman. From March, 1903, until March, 1904, he was employed by the Mesta Machine Company as designing draftsman. While he was with the Mesta Machine Company, Mr. Myron was always alert for further knowledge and advancement. In March, 1904, he became designing draftsman for the Pittsburgh Filter Company of Pittsburgh. He remained with this company for sixteen years, advancing from designing draftsman to chief draftsman, chief engineer, secretary, and general manager of the Oil City (Pa.) manufacturing plant of the enlarged Pittsburgh Filter and Engineering Company. During his many years with the Pittsburgh Filter and Engineering Company, Mr. Myron had charge of the design and construction of many outstanding municipal water filtration plants—in all, more than two hundred municipal plants. In addition to design and construction, he directed the design and manufacture of all types of water purification plant equipment.

In March, 1920, he left the Pittsburgh Filter and Engineering Company to enter into a partnership with Leo Hudson of Pittsburgh. The firm specialized in water works and sewerage projects. During the ten years, until 1930, he supervised the design and the construction of many water works projects. He was intensely concerned with the best interests of his clients, who remained his lifelong friends.

In January, 1930, he joined F. B. Leopold Company, Inc., of Pittsburgh. Many of his former associates in the Pittsburgh Filter and Engineering Company (which had dissolved in 1922) were also in the employ of this company. Mr. Myron was interested not only in the design of water filtration plants, but in their actual construction and in the design and constant improvement of water filtration plant equipment.

During the early years of the economic depression and until December 7, 1941, the water works field suffered possibly more than a great many other activities. Many adjustments and readjustments occurred during the emergency period. Since Mr. Myron was intensely interested in all phases of water works development, this situation without a doubt helped to cause his early death.

Like that of other companies, the business of the F. B. Leopold Company, Inc., increased greatly due to wartime demands, following the attack on Pearl Harbor, Hawaii, on December 7, 1941. This increased activity found a great response in the efforts of Mr. Myron, and, disregarding all warnings, he, like many others, tried to do more than usual, only aggravating his then unknown ill health. When he finally consulted a physician, it was too late to repair the damage done by his intense interest and relentless energy.

During his thirteen years with F. B. Leopold Company, Inc., Mr. Myron made outstanding contributions—innovations and improved methods and equipment—to the water treatment field. He supervised all engineering work and construction and designing, as well as serving as vice-president and secretary. At his death he was vice-president and treasurer in complete charge of the company's operations. During his many years in the water works field, he avoided publicity and personal promotion, being at all times more interested in his work and the over-all good that his efforts might produce.

Although Mr. Myron took an active part in professional affairs, he remained out of the limelight. His only hobby was his sincere interest in engineering and the welfare of his family. His vacations were few, and they were usually spent in behalf of others. Mr. Myron derived his greatest pleasure from helping other people.

Mr. Myron was one of the first residents of Brookline (later part of Pittsburgh). He was instrumental in the formation of the Brookline Savings and Trust Company and was secretary and director from its inception in 1926. He helped to found the Brookline Building and Loan Association of which he was a director from its beginning in 1922.

On June 28, 1905, Mr. Myron was married to Rose A. Kelly of Pittsburgh. Besides his widow, he is survived by three daughters, Grace, Helen, and Rita; two sons, John F., a cadet at the United States Military Academy in West Point, N. Y., and Thomas L., Lieutenant, U. S. Army; and a sister, Nellie.

Mr. Myron was elected a Member of the American Society of Civil Engineers on April 19, 1920.

DAVID LEONARD NEUMAN, M. Am. Soc. C. E.[1]

Died November 24, 1944

David Leonard Neuman, the son of Samuel and Ernestine (Rosette) Neuman, was born in New York, N. Y., on August 27, 1891. After being educated in the local public schools, he entered Columbia University, also in New York City, from which he was graduated in 1913 with the degree of Civil Engineer. Following his graduation, he was engaged on various types of construction work, beginning as an instrumentman and advancing to construction engineer.

Mr. Neuman joined the New York National Guard on July 4, 1916, and served as a Private, First Class, with Company A of the Twenty-Second Engineers during the border dispute with Mexico. On March 6, 1917, he was commissioned a Second Lieutenant in the Officers Reserve Corps and subsequently was appointed to the Corps of Engineers of the United States Army. He was promoted to the rank of Captain on June 4, 1917, and was assigned to Camp Forrest, Georgia, as Executive Officer.

---

[1] Memoir prepared by C. L. Hall, M. Am. Soc. C. E.

From 1919 to 1922, Captain Neuman was in charge of surveying military roads in Panama. In 1923 he was graduated from the course for company officers given by the Engineer School at Fort Belvoir, Va., and was assigned to Fort Sam Houston, Tex. In 1926 he became Assistant to the District Engineer of the U. S. Engineer Office in Milwaukee, Wis. In 1928 he was appointed Engineer Supply Officer of the Columbus General Depot at Columbus, Ohio. He successfully completed the course at the Command and General Staff School, Fort Leavenworth, Kans., in 1933. On March 1, 1934, he was promoted to Major and assumed command of the First Battalion, Thirteen Engineers, at Fort Belvoir.

In 1935 Major Neuman became Assistant to the Division Engineer, South Atlantic Division, in Atlanta, Ga. He was promoted to the permanent rank of Lieutenant Colonel on July 1, 1940, and returned to Fort Belvoir to assume command of the Second Training Group, Engineer Reserve Training Corps. He was promoted to the temporary rank of Colonel in the Army of the United States on February 1, 1942.

In March, 1942, Colonel Neuman was placed in command of the Ninety-Fifth Engineer Regiment in the South Sector of the Alcan Highway in Canada. Suffering from a knee injury five months later, he was sent to Walter Reed Hospital in Washington, D. C., for treatment. Upon recovery, Colonel Neuman returned to the Columbus Army Service Forces Depot as Engineer Supply Officer. In November, 1943, he was appointed Commanding Officer of the Marion Engineer Depot in Marion, Ohio, where his untimely death occurred while in the performance of duty on November 24, 1944. He was buried with full military honors in Arlington National Cemetery in Arlington, Va., on November 28, 1944.

Colonel Neuman served the United States faithfully as an officer in the Corps of Engineers, and his loss is keenly felt by his friends in and out of the service. He died, as he would have wished, serving his country in time of war.

In 1929 Colonel Neuman was married to Ruth Cott of Columbus, Ohio. He is survived by his widow; a son, Robert Neumann; and two daughters, Myrna and Marcia Neuman.

He was a charter member of the Society of American Military Engineers.

Colonel Neuman was elected a Junior of the American Society of Civil Engineers on February 4, 1914; an Associate Member on November 9, 1920; and a Member on April 13, 1936.

JOSEPH PETTIS NEWELL, M. Am. Soc. C. E.[1]

DIED DECEMBER 5, 1938

Joseph Pettis Newell was born on May 11, 1866, at Mt. Tabor (later within the corporate limits of Portland, Ore.), on a homestead which was the end of the covered wagon trail for his parents, John S. and Sarah E. (Kearns) Newell. They had arrived, strangers to each other, from Iowa and Indiana in 1852, and were principals in the first wedding at Mt. Tabor.

When Joe had finished his education in the log schoolhouse of the Mt. Tabor neighborhood, there was ne'er a bridge across the Willamette River. He rode a pony four miles and ferried to attend the Portland High School. In 1884 he matriculated at Massachusetts Institute of Technology (M. I. T.) in Boston, Mass., and is believed to have been the first student from the "Oregon Country" to slake his thirst for knowledge at that celebrated school of scientific learning. In that day "Boston Tech" was a far cry from Mt. Tabor in Oregon, notably so for young Joe Newell who had neither New England pedigree, nor engineering heritage, nor come-by patrimony to dissipate. Getting there however was a sign of a dominant engineering bent in a budding mind that visioned opportunity in engineering in a promising wilderness. Indeed he had decided on his vocation when he entered high school.

Definitely his thinking throughout a long career was alined to "tasks of applying means to definite ends in the material life of men under the limitations of economic laws."[2] Note especially the word "task." J. P. Newell could go into theories with you but he was essentially a doer, an evaluator, a man of direct methods and processes toward concrete ends. He was intrinsically genuine and substantial, gifted with a probity both moral and intellectual that formed the warp of his homespun character. The weft was never coarse nor common nor flashy.

"Native" describes the career of Joe Newell. He was born, grew seventy-two inches tall, lived all of his seventy-two years, and died in Portland, while the population of that city waxed from six thousand to three hundred and fifty thousand. To attain the eminence that he reached in his profession he naturally moved in a larger circle than the compass of the home town, but was never away from home for any permanency. For him ever there was no place like home. On the other hand, he gave no impression of provincialism.

He was at M. I. T. three years, and in the spring of 1887 had practically completed a four-year course, but was not granted a diploma. He might have graduated with his class cum laude with a bit of readying for commencement, but the grain of Boston had been garnered, he needed no hallmark, he had come of age and was busily engaged in his life's work. He had a job as draftsman with the Cincinnati Southern Railway, and held it a year or so; then in

---

[1] Memoir prepared by C. P. Keyser, M. Am. Soc. C. E.

[2] From a definition by Nicholas Murray Butler, *Engineering News-Record*, January 24, 1924, p. 161.

1888 he returned to Oregon and grew up with the Oregon Railway and Navigation Company which he served, with some minor leaves, until 1907.

In the 80's and 90's, before the Harriman merger, these lines had seen an interesting two decades building and rebuilding under William H. Kennedy,[3] M. Am. Soc. C. E., as chief engineer. From him Newell got his training in practical problems of railroad location and construction, along with some dogma from A. M. Wellington's "Economic Theory." Writing of Kennedy in his memoir[4] the late Virgil G. Bogue, M. Am. Soc. C. E., states, "He may safely be called one of the great engineers of his time and country." Newell was an apt scholar, and became one of his chief's most able assistants, handling most important assignments, main line, branch, and terminals, location, construction, and reconstruction. During the last three years of his service with the Oregon Railway and Navigation Company he was division engineer of the Oregon Division, which comprised 600 miles and included the Portland rail and water terminals.

In his railroading experience he demonstrated initiative, ingenuity, and administrative ability in the full measure that it required. For instance, when in his early track work, he came across trackmen with lining bars "easing" the points of curve and tangency with more sense than science, he deduced an equation and tabulated a set of graduated shifts or radial offsets with corresponding superelevations. His method was simple enough for use by track foremen without the benefit of engineer surveyors.[5] It proved so satisfactory that he converted it to a set of spirals stated in a flexible system of deflections from tangent for transit setting, made the Newell spiral standard for the Oregon Railway and Navigation Company, and over a period of years got the entire system properly spiraled. The late Elliot Holbrook, M. Am. Soc. C. E., developed the same curve, an approximation to the cubic parabola, about the same time,[6] unbeknown to Newell, and it was later elaborated and a working manual[7] was prepared by Prof. Arthur Newell Talbot,[8] Past-President and Hon. M. Am. Soc. C. E.

He was smart, and ready and able in emergency. Once upon a time, a short time in spite of his vigilance, a main line tunnel collapse became suddenly imminent, and would have caused a serious interruption of traffic if Newell, the division engineer right on the job, had not thrown an 18° "shoofly" around it in time to save the day. It was merely an incident that the master mechanic protested that his new long-wheel-base locomotives would not take a curve of so short a radius; but Newell had reckoned the gage spread and it all worked out satisfactorily after he had seen to it that more slack was allowed in some peculiar stay chains on the engine trucks—something that mere civil engineers were not supposed to understand or to tamper with. Virtue was its own reward in this instance, as in many another, for the general superintendent took all of the credit and Joe remarked dryly, "Everybody was satisfied."

A romantic story has been written, founded on the Indian legend of the Bridge of the Gods. The story prevails that there was a natural bridge across the Columbia River where it has cut through the backbone of the Cascade range down to sea level 100 miles inland from its mouth. According to J. P. Newell there might have been a natural bridge, and it might have afforded a crossing for the aborigines. He thought, however, that he was not bridge engineer enough to attempt to restore it even in his mind's eye, with the abutments now standing three thousand feet high and nearly five miles apart. But he was long and intimately connected with railways through the gorge on both banks of the river—railways that had not waited for the ground to come to rest following the failure of the bridge, mythical or actual.

He was well informed on the ostensive causes of the storied failure, or, more to the point, what to do to keep the tracks in alinement as they traversed the restless banks of the mighty stream. The Indians might hand down a story, but it was characteristic of Newell to garner and interpret the indications, and one could well believe what he reported even to his observations on the Indians themselves, to whom he was no stranger.

In 1907 he was 41 years old, ripe in experience, and exceptionally well informed on the economics of transportation in particular, and utilities in general. He quit the railroad, and hung out his shingle in Portland as a consulting engineer, an event in his life that marked decisively the turn from the formative to the definitive stage of his career.

Thus he was available as a qualified expert to enter a long tenure with the Oregon (State) Public Service Commission where he rendered yeoman service. Perhaps his most conspicuous achievement for his state and community was the bringing of victory in the celebrated Columbia Basin rate case in 1919, which was decided by the Interstate Commerce Commission mainly on Newell's analysis of the basic considerations in the points at issue. His studies of "equated mileage" disclosed unanswerably the difference in tonnage costs via inexpensive and safe transit through the gorge of the Columbia on water grades to and from maritime connection at Portland, as compared with the haul over the Cascade mountains to Puget Sound ports. Incidentally, in 1917 he wrote a Report to the Oregon Public Service Commission entitled "Study of Cost of Freight Service, O. W. R. & N. Ry.," which would have made Newell's reputation even if he had not brought victory at said hearing, or later figured so prominently in Canadian railway arbitration.

In 1918 the rate structure of the three main railway systems of Canada had become involved and out of harmony; at least two were fraught with crucial financial difficulties. So a thoroughgoing investigation and arbitration were brought about through legislative action of the National Parliament by appointment of a special Arbitration Board. To amass and evaluate the data pursuant to the findings it was necessary to engage an engineer competent in valuation and operation cost analysis; and particularly one who could report authoritatively the underlying basis of rate making. In this case rates were complicated not only within Canada but also by transhipment over rail connections in the United States, and the implications reflected on obligations to stockholders and also to wage interests of employees. It was a momentous job which began by sifting the Canadian Northern and later worked over the Grand Trunk. The officials of Ottawa, Ont., Canada, asked the United States Interstate Commerce Commission to recommend three engineers for them to choose from. Mr. Newell was the first and most highly recommended of the three names submitted and so he was engaged by the Canadian Government first from February to June, 1918, on the Canadian Northern Railway Arbitration at Toronto, Ont., Canada, and again from May, 1920, to July 1921, on the Grand Trunk Railway Arbitration at Montreal, Que., Canada. Mr. Newell was named the Canadian Government's official engineer in taking over the Grand Trunk.

Out of the mass of fact-finding in these cases he prepared a paper[9] which won for him the first award of the Society's A. M. Wellington prize instituted by *Engineering News-Record.*

He was intimately connected with the board and committee workings of the Portland City Club, an unchartered civic institution, notable for nonpartisan findings in matters of local governmental processes, city planning, etc., and he served one year as its president. He was a member of the National Conference on City Planning. He was the first chairman and thereafter the perennial consultant to the Portland City Planning Commission, and made cogent reports on transportation and traffic, particularly highway, rail, and water borne, in relation to major schemes of articulation and terminal factors as affecting land use of urban areas. He was one of the founders of the Portland (Ore.) Section of the Society (1913), and continued to be an active Past-President, doing his part of the cambium activities that keep these limbs of the parent trunk from dying of dry rot. He headed a committee of the Portland Section that made an exhaustive investigation and printed a report in 1915 on causes and remedies of public works unemployment, really an analysis of fluctuations in demand on the man-power supply, entitled: "Report on Winter Unemployment." He was an active member of the Engineering Institute of Canada.

Nominally a Republican, he "had no truck" with the slough of politics, although ever constant in duties of citizenship. He favored prohibition and was an orthodox Methodist, but his ways "were ways of pleasantness, and all his paths were peace." A man of high ideals and no illusions, he did not quarrel but lived in a human world content and self-sufficient. If he could be accused of a hobby it was critical and intensive study of the world's "best seller" which he engaged in to the extent of teaching Sunday School classes and even unto delving into Greek for a working knowledge in order to interpret the original text of the New Testament for his own edification. His recreation was in useful toil in his garden or in voracious reading.

He had in nice combination a faculty for rapid assimilation and an exceptionally accurate and retentive memory. Few people in everyday and upper walks of life had a tidier vocabulary, and, even fewer, a more facile flow of clear and simple thought-expressing language. He employed few expletives and conceits of expression, and was not much given to metaphor. Early in life he became proficient in shorthand, and habitually used it in composition, side notes, and memoranda. He kept a diary in shorthand consistently. His amanuensis could transcribe his notes as readily as her own, a real advantage in reaping a busy man's mental harvest. It was a pleasure to "listen in" on his dictation.

---

[9] "Analysis of Cost of Freight Service, Grand Trunk Railway Company of Canada," by J. P. Newell, *Transactions*, Am. Soc. C. E., Vol. LXXXVI (1923), p. 351.

He enjoyed legitimate drama, but was not intrigued by movies. He abhorred idleness in any form like nature abhors a vacuum, so much so that he did not even want to think of taking a vacation; and he couldn't be bothered with insomnia. He did not fret himself with counting sheep or worry about wakefulness. As he put it, he rested in bed while he took advantage of the quiet to think constructively, glad to avail himself of the opportunity. But mind you, he had no addictions except honest hard work, not even to mild stimulants. "Hells' bells" never jangled him out of his mental equilibrium. Except for an injury to a knee late in life which laid him up for a time, he was always abundantly able to go about and get where he wanted to be.

He had little interest in gadgets for his personal use. A rapid sure-fire mental calculator, he found no need for a slide rule. He never owned or operated an automobile, although he did not underestimate or fail to appreciate its value as a modern convenience to a useful, as differentiated from a wastrel, purpose. To him an artificial thing of beauty might be a joy forever only if it had an excuse, or more properly a cause, in usefulness. But the pristine beauty of a young tamarack—that would be an unalloyed joy.

He was gifted with a keen sense of humor and a ready dry wit. He was the sort of solid individual that seemed to have no loopholes for an antagonist to work on—that is, he would be responsive, generous, and deferential, but like all men of caliber, was not easily influenced. Yet withal he was interesting, and agreeable in his contacts, the kind of personality that any one could enjoy conversing with.

The summit of his career was marked by the Canadian Railway Arbitration engagement referred to previously, but perhaps the most flattering offer he ever received came when he was nearing sixty. This was an overture from the Persian Government to reconstruct and modernize their national transportation system on his own terms. After considerable study he declined the offer. At the time he was engrossed in another large thoroughgoing utility appraisal, but it will not enhance the history to hazard that he might have delegated the drudgery of that engagement. Then why did desert Persia fail to lure him from verdant Oregon? Deponent sayeth not in very sooth; but to one who knew him well, a sufficient answer would be not difficult to ascribe. Civil engineers, notably those who become eminent in their profession, are the sort of stones that go rolling more or less. Newell was not given naturally to temporary sojourning. His locale remained centered in the home life, private and public, of his native heath all of his days. He went on living with the same bride, with one son to bless the union, in the home with spacious garden that he brought her to from southern Oregon in 1892, until deaths did part in 1938, hers in July, his in December, both suddenly.

All the while he kept up the place joyously by his own toil and care. He was a pillar of his church a few blocks away. He was public minded in his professional service; sound and clearheaded and essential in his numerous civic activities. Never self seeking nor a weather vane, his friendship and his friendships were valued; in fine, a generous and constant contributor to the good life and toward its betterment in his home town and state.

There was no outcrop from his make-up of a lust for power or glory or pelf; seemingly indifferent to fame, he was ever content with life's compensations where he chose to find them. So—lovely mosses had gathered on this stone and it had settled in situ in threescore years. Shouldn't it have taken some prizing to dislodge it and set it going toward remote Persia?

He lived in an abiding faith in the ultimate worth of mankind, and the fitness of mundane cause and effect, neither a borrower nor a lender of trouble. Here was one of those rare characters of ability and distinction, who move ever forward in full power, unaccused of envy, avarice, or a "yen" to glitter. An abstemious thoroughgoing person, nothing small, who wrought and dwelt constantly for the benefit of the people and the region to which he belonged.

Mr. Newell was elected a Member of the American Society of Civil Engineers on October 2, 1907.

WALTER HENRY NORRIS, M. Am. Soc. C. E.[1]

DIED JULY 11, 1942

Walter Henry Norris, the son of Edward John and Clarissa (Norton) Norris, was born on March 6, 1870, in Charlestown (Boston), Mass. He was graduated from the Massachusetts Institute of Technology at Boston in 1893 with the degree of Bachelor of Science in Civil Engineering. During college vacations he worked for the Canadian Bridge and Iron Company of Montreal, Que., Canada, and for the St. Johnsbury and Lake Champlain Railroad Company as rodman and instrumentman.

After graduation, Mr. Norris entered the Engineering Department of the Boston and Maine Railroad. He remained with this organization until 1909. From June, 1893, to January, 1899, he was draftsman in the Bridge Department, investigating the strength of structures and inspecting bridges in the field. From January, 1899, to August, 1909, he was assistant bridge engineer, designing and preparing working plans for grade-crossing eliminations, freight houses, engine houses, coaling plants, and docks.

In 1909 Mr. Norris joined the engineering department of the Maine Central Railroad Company and remained with that company until his death. From 1909 to May, 1933, he was bridge engineer, and, from 1933 to 1939, assistant engineer of structures. From 1939 until his death he was consulting structural engineer.

---

[1] Memoir prepared by Edward M. Hunt, M. Am. Soc. C. E.

The largest of the many bridges Mr. Norris designed for the Maine Central Railroad Company is the five-span Sheepscot River Bridge at Wiscasset, Me. This bridge, completed in 1916, consists of two through-plate girder spans, one of which is a draw span, and three riveted truss spans, one of which is 400 ft long.

Mr. Norris designed and supervised the reinforcement of the Frankenstein Trestle near Crawford Notch in the White Mountains of New Hampshire. This work, completed in 1930, was done without interrupting train service, and showed superior ability in treating difficult design problems.

In 1920 the Hon. Percival P. Baxter, then Governor of Maine, appointed Mr. Norris on a three-man board of engineers for the construction of the highway memorial bridge across Portsmouth Harbor between Maine and New Hampshire. The board employed the firm of Waddell and Hardesty, of New York, N. Y., to design the bridge, which was built by the American Bridge Company and completed in 1923 at a cost of $1,500,000.

Mr. Norris was a conscientious worker and loyal to the teachings of his instructors and to the natural laws that govern good design. He deemed steel the best medium for strength, endurance, and economy in heavy bridges. To his eye, a well-designed bridge, although plain and severe in appearance, was beautiful because it served a useful purpose. Embellishment he regarded as extravagance.

His domestic and social principles were puritan like those of his ancestors. He sought to teach young people that a firm financial foundation is a prime requisite for life. Mr. Norris had deep sympathy and deemed a timely lift to an associate a pleasure to the giver. He had been a member of the Congregational Church since 1889, and expressed his religion in practical ways that endeared him to many. His courage, cheerful disposition, and spontaneous sense of humor were appreciated by his associates.

In 1897 Mr. Norris was married to Effie L. Shapleigh, who survives him, as do two daughters, Elizabeth (Mrs. D. Kilton Andrew) and Katherine Norris; and two sons, Edward J. Norris (Captain, United States Army Engineer Corps) and Emerson S. Norris. Mr. Norris' sons and his brothers (the late Webster Norris and the late George L. Norris) all were graduated from Massachusetts Institute of Technology.

Mr. Norris was elected an Associate Member of the American Society of Civil Engineers on September 6, 1905, and a Member on June 12, 1939.

CLIFFORD OLDER, M. Am. Soc. C. E.[1]

DIED NOVEMBER 28, 1943

Clifford Older was born in Lincoln, Adams County, Wis., on November 17, 1876, the son of Milton DeWitt and Elizabeth Ann (Clark) Older. His parents soon moved to Portage, Wis., where he grew up and attended high school. He chose engineering as his life work and received his training at the University of Wisconsin in Madison, being graduated in 1900 with the degree of Bachelor of Science in Civil Engineering.

From 1900 to 1906 Mr. Older was employed on railroad work—for the Pennsylvania Railroad Company, the Wabash-Pittsburgh Terminal Railroad Company, and the Chicago and Alton Railroad Company. In 1906, five months after the organization of the Illinois Highway Commission, Mr. Older was appointed Bridge Engineer for the State of Illinois. At that time very few roads in Illinois were improved, and much of his time was devoted to emphasizing to township and county officials and to the general public the benefits of permanent road improvements. He initiated and developed the construction of reinforced concrete bridges in Illinois and did much to popularize such construction. In 1917 he was appointed by the Hon. Frank E. Lowden, then Governor of Illinois, as Chief Highway Engineer. In that capacity he continued to apply the initiative and originality that had characterized his work as Bridge Engineer.

Mr. Older participated in the formulation of the $60,000,000 Bond Issue Road Law—the first step in making a paved road system possible in Illinois. Looking forward to the thousands of miles of road to be built and to the constantly increasing traffic, he conceived an extensive research project to determine what design and type of construction would be best and most economical. Under his direction the famous Bates Road Tests were planned and executed. Small sections of various types of pavement were built where traffic could be completely controlled and were subjected to actual truck traffic. Numerous field observations were made and laboratory tests conducted to check the behavior of the sixty-seven sections. When the research was completed, the profession possessed a scientific basis for designing pavements based on tests made under actual traffic conditions. International recognition was given to the importance of this study. Designs of pavement slabs developed as the result of this research were adopted not only throughout Illinois but, to a large extent, throughout the entire world.

In 1924 Mr. Older resigned as Chief Highway Engineer of Illinois to enter private practice as senior partner of the firm of Consoer, Older and Quinlan, in Chicago, Ill. During ten years of active service with this firm, he directed a large variety of engineering design and construction and also conceived and developed several successful patented appliances in the highway construction field. After his retirement from this firm in 1934, he served as consultant on highways for several railroad associations and worked on inventions connected with rigid pavement design.

---

[1] Memoir prepared by George O. Consoer, M. Am. Soc. C. E.

On May 28, 1903, in Lowville, Wis., he was married to Kitty May Drake. He is survived by his widow and their five children—Fern Elizabeth (Mrs. Harold Lundberg); Kitty Beatrice (Mrs. Lloyd Quayle); Clifford D., Lieutenant in the U. S. Navy (U.S.N.R.), serving in the South Pacific area; D. Drake; and Grenfell.

Always interested in photography, Mr. Older enjoyed the technical problems of color photography and secured patents on two of his ideas in this field. Although barred by increasing lameness from many activities, he took many automobile trips with Mrs. Older through the United States. Mr. Older's keen mind and love of nature made each excursion a delightful experience.

Mr. Older was a member of the Western Society of Engineers, the American Society of Municipal Engineers, the Mississippi Valley Conference of State Highway Departments, the American Society of State Highway Officials, and the American Society for Testing Materials. He served for many years on the Design Commission of the Highway Research Board of the National Research Council. He belonged to the Masonic Order and the Methodist Church.

Occasionally one meets a man of such marked ability, character, and affability that he commands immediate respect and also induces a warm personal liking. Mr. Older was a man of this type. As a public servant, he was a shining example of integrity, devotion to duty, and technical competence. On his associates he left an indelible impression of kindliness, unfailing courtesy, and adherence to high ideals.

Mr. Older was elected an Associate Member of the American Society of Civil Engineers on October 4, 1905, and a Member on July 7, 1915. He became a Life Member in 1940.

DAVID KIRK ORR, M. Am. Soc. C. E.[1]

DIED NOVEMBER 9, 1943

David Kirk Orr was born on November 24, 1865, in Allegheny City (later the north side of Pittsburgh), Pa., the son of Samuel Mowry Orr and Jane (Kirk) Orr.

He was educated in the public schools of Allegheny City; at the Western University of Pennsylvania (later the University of Pittsburgh) in Pittsburgh; and at Geneva College in Beaver Falls, Pa., being graduated from the latter with the degree of Bachelor of Arts in 1889.

Mr. Orr's professional career was devoted to railroading. First, in 1889 he was employed by the Norfolk and Western Railway Company as topographer's assistant. In 1891 he obtained a position with the Pittsburgh and

---

[1] Memoir prepared by G. H. Burnette, M. Am. Soc. C. E., and J. W. Boyd, Supt., Monongahela Railway Co., Brownsville, Pa.

Lake Erie Railroad Company as instrumentman. From 1893 to 1901 he was associated with David B. Kirk and Company, flour blenders and exporters of Kansas City, Mo. In 1901 he returned to the Pittsburgh and Lake Erie Railroad Company as assistant engineer, remaining until the Monongahela Railroad Company was organized in 1903.

Beginning as engineer for the Monongahela Railroad (later Monongahela Railway) Company, he advanced to assistant chief engineer in charge of construction and maintenance. Under his guidance, extensions were made to the main line and several branches during this period. In 1919 he was promoted to superintendent. Following a reorganization in 1933, he was made roadmaster. He retired on June 1, 1937, after nearly half a century of railroading.

Mr. Orr was known affectionately as "D.K." to old and young alike. He was identified with almost every community activity and received a citation from the local American Legion Post for outstanding community service.

The first president of the Brownsville (Pa.) Rotary Club, at the time of his death he had been serving as the club's executive secretary. Also he was secretary-treasurer of the Brownsville Board of Trade; a member of the Session of the First Presbyterian Church; past-president of the South Brownsville School Board, Brownsville Trust Company, South Brownsville Improvement Company, and Brownsville Athletic Association; and treasurer of the Ward Supply Company.

Mr. Orr belonged to a number of fraternal organizations and lodges including F. and A. M. (32d Degree), the Shrine, Benevolent and Protective Order of Elks, Nemacolin (Pa.) and Morgantown (W. Va.) country clubs, Engineering Society of Western Pennsylvania, American Railway Engineering Association, and Railway Club of Pittsburgh.

On September 14, 1897, he was married to Margaret McMaster at Broughton, Pa. He is survived by three sons—Gilbert, Samuel, and John—and two daughters—Jennie and Mary.

A man of simple tastes, high ideals, and integrity, his life was filled with active service to his fellow men. All who knew Mr. Orr mourn the loss of an able, efficient, and wise associate, counselor, and friend.

Mr. Orr was elected a Member of the American Society of Civil Engineers on April 4, 1911. He became a Life Member in 1936.

GEORGE ALEXANDER ORROK, M. Am. Soc. C. E.[1]

DIED APRIL 6, 1944

George Alexander Orrok ("Uncle George," as many of his intimates affectionately called him) was an essence of his ancestry—a finely distilled and stimulating essence, such as cognac from wine or Calvados from Norman cider.

---

[1] Memoir prepared by Dugald C. Jackson, M. Am. Soc. C. E.

Few came to know his full and sparkling merit until after extended acquaintance.

He was born at Dorchester, Mass., on July 3, 1867, a descendant of old-time European and American families. Late in the eighteenth century a member of the Orrok family came to America from Great Britain, but presumably Mr. Orrok's paternal ancestors migrated to England from Denmark during the Danish invasion in about 900. A village east of Edinburgh still bears the name of Orrok. These people were seamen, merchants, business men, and mechanics. Alexander Orrok came to America; family tradition associates him with Paul Revere and with the Boston Tea Party. He, like others of the family, was a skilled mechanic. His grandson, James, married Laura Davenport, and "Uncle George" was their son. A Davenport relative is reputed to have been aide of General Lafayette during the Revolutionary War. These American ancestors were from Boston, Mass., and Dorchester, and generally seem also to have been skilled mechanics in ship chandlery or ship operation. George Orrok's father was a heavy, strong man, who was a member of one of the volunteer fire companies of the day and is said to have lifted the rear wheel of a three-horse steam fire engine for a stunt.

His mother died when George Orrok was four years old, and he and a younger brother were mostly cared for by their father. A younger sister was raised by relatives. With the interested attention of father and aunts, young George grew up through an active and happy but very busy life. By the time he was of school age he was largely earning his own living and also had become adept at amateur theatricals, a lover of instrumental music, singing, and dancing, and a follower of tennis. He undertook to play various musical instruments and at one time supported himself by playing the cornet in a brass band. In later years he played the flute and became a member of the New York (N. Y.) Flute Club.

Mr. Orrok prepared for college at the Dorchester Grammar School and the Mechanic Arts High School of Boston, with the summers affording him foundry, wagon shop, tack factory, and other varied employment. His plan for life was to become a steel chemist and he entered Massachusetts Institute of Technology at Boston in 1885, enrolling in the chemistry course; but providence thwarted the ambition. In 1888, on account of his eyes, the family physician directed him to work no more in laboratories and to secure employment that would keep him outdoors as much as possible.

Thereupon, Mr. Orrok started upon four years of a somewhat gypsy series of engineeering employment which took him from Alabama, to Wisconsin, to Utah, and back to New England. Then he began the fine, creative professional career in engineering that ultimately led to the great distinction of honorary membership in the American Society of Mechanical Engineers, a society of which he became a member in 1902 and for which he had great affection.

Having returned to Boston, he was employed in 1892 by F. S. Pearson,[2] M. Am. Soc. C. E., who was a distinguished consulting engineer in the electric and cable street railway fields, and whose particular clients were Henry M.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXVII (1924), p. 1402.

Whitney of Boston and William C. Whitney of New York. As the Messrs. Whitney had wide interests beyond their own localities and also beyond the street railway field, Mr. Orrok had a roving commission, ranging from examining coal mines in Rhode Island, extensive designing of coal-mine developments in Nova Scotia, designing and supervising the construction of a cable railway in New York City, designing and supervising underground trolley street railways in New York City, to designing exceptionally large coal piers in Nova Scotia, coal-carrying ships, and mine hoists for the coal mines. Associated with all these projects were a variety of others (mostly in Nova Scotia), which required a high degree of initiative as well as mechanical skill.

Returning to Mr. Pearson's main office in New York City, Mr. Orrok worked on electric power stations for street railways from New York City to Winnipeg, Man., Canada; sugar refineries at St. John, N. B., Canada, and Baltimore, Md.; an underground trolley system for Birmingham, England; and various projects for Brazil, Cuba, and the Island of Jamaica, B. W. I. When Mr. Pearson was taken ill and retired from his practice as a consulting engineer, Mr. Orrok, after some intervening employment, in the spring of 1898 was engaged by the New York Edison Company, which had great problems regarding its growing electric power plants and distribution system—all of them in the hands of the brilliant John Van Vleck, consulting engineer for the company. At this time the New York Edison Company was concentrating its generation of electric power in great water-side alternating-current generating plants and substituting rotary-converter substations for the old-time direct-current primary generating stations. In all this novel work, Mr. Orrok was in his preferred element—on work which required great concentration of effort but which returned great satisfaction from accomplishment. In 1928 he established his own office as consulting engineer, under the name of Orrok, Myers and Shoudy (later Orrok and Myers Associates). Clients came to this firm from many parts of the United States and various foreign countries.

Mr. Orrok always retained his intimate contact with the mechanical engineering affairs of the New York Edison Company. His was a long and contributive career in electric power plant design, with particular emphasis on the thermodynamic aspects. Thus, when the growing use of higher pressures in the steam boilers of power plants became important, Mr. Orrok sought adequate information regarding the qualities of steam at ultrahigh pressures. He therefore participated in the development of extended and improved steam tables—a piece of eminent research in which he gained the adherence and aid of important investigators in the United States and in England. Financial contributions for the study were obtained from educational institutions and from manufacturing companies interested in the improvement of thermodynamic equipment. The work was conducted under the patronage of a committee of the American Society of Mechanical Engineers, which society is proud of the achievement.

Becoming interested in the needs of World War II, Mr. Orrok joined the firm of Binger-O'Connor-Orrok to deal with important problems of design and construction facing the armed forces of the United States. Many of these problems called for unusual initiative.

As chairman of committees and member of other committees, especially of the American Society of Mechanical Engineers, he contributed much to the progress of engineering practice. He was the author of articles in the Proceedings of the Societies to which he belonged. Jointly with the late Dean Robert H. Fernald of the University of Pennsylvania at Philadelphia, he wrote the book entitled "Engineering of Power Plants."[3] His Newcomen Society essay entitled "Engineering Recollections, 1868–1898" is a delicious exposition of his engineering philosophy, which arose from his thrifty Scotch ancestry and his own notable original mindedness.

Mr. Orrok possessed an interesting versatility in general learning; and, with his intimates, he loved to illustrate his "shop talk" with quotations from a wide range of classical and modern literature, all apposite and impressive. As a fisherman, he was unusually familiar with the various fish and shell fish of American waters and also in the general aspects of foods. These qualities attracted to him a group of men who habitually took lunch at a round table in the Engineers' Club (New York), for whom he was the admired companion and wit.

In the days when he lived in an apartment near Grand Central Station in New York City, he invited his friends arriving from out of town to breakfast with him, and to them Mrs. Orrok hospitably served stacks of tempting hot cakes and maple syrup with delicious coffee. Together with his cherished wife and son, these breakfast-enjoying friends seemed to compose his family. He was not a physically robust man, but he was an ardent attendant at engineering meetings. In the evenings he loved best to rest at home where he read with pleasure a wide range of ancient and modern literature, or played lively tunes on his flute. His was a soul of restful sociability but of distinguished initiative in engineering professional affairs.

Mr. Orrok became a member of the American Society of Mechanical Engineers in 1902 and a fellow in 1936. In 1936 he was elected an honorary member of that society—a distinguished honor which he greatly appreciated. He also belonged to the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Institute of Consulting Engineers, the Institution of Mechanical Engineers (Great Britain), and other societies which cherished his membership. The Stevens Institute of Technology in Hoboken, N. J., conferred on him the honorary degree of Mechanical Engineer. He lectured on steam engineering and power plant engineering at Yale University in New Haven, Conn.; Harvard University in Cambridge, Mass.; the University of Pennsylvania in Philadelphia; and at other institutions. He was a Brackett Lecturer at Princeton University in Princeton, N. J.; and, from 1911 to 1914, he taught steam engineering in the Polytechnic Institute of Brooklyn at Brooklyn, N. Y.

On December 24, 1898, Mr. Orrok was married to Jessie Waldo, who died in February, 1921. George A. Orrok, Jr., their son, follows in his father's footsteps as engineer for a great electric power company. Mr. Orrok was married on October 20, 1923, to Elene E. Geer, who survives him. He owned a place in Connecticut where he enjoyed summer holidays, often with his son and family, but the abode which many of his friends knew was the apartment in New York City.

---

[3] "Engineering of Power Plants," by Robert H. Fernald and George A. Orrok, McGraw-Hill Book Co., Inc., New York, N. Y., 3d Ed., 1927.

Mr. Orrok was elected a Member of the American Society of Civil Engineers on June 6, 1906.

ARTHUR EDMUND OWEN, M. Am. Soc. C. E.[1]

DIED MARCH 21, 1944

Arthur Edmund Owen was one of the intrepid group of railroad men who never considered personal comfort before duty. Thus, on March 21, 1944, at the end of a busy day of office routine and executive conferences, his strength was too depleted to do more than relax into the eternal sleep from which no man may be awakened by earthly commands. He died in a railway coach of the "Crusader" near Elizabeth, N. J., on the train that usually carried him to his home at Abington, Pa.

Arthur Edmund Owen was born at Montclair, N. J., on January 19, 1876. His parents, James Owen and Mary Caroline (Dunham) Owen, were certain one more civil engineer had been born into the family. His father, who had emigrated from London, England, where he had been graduated from London University, for more than forty years was county engineer of Essex County, New Jersey, building many famous roads and writing authoritative articles for magazines and technical journals on road building and allied topics. Mary Caroline Dunham Owen was descended from a long line of colonial ancestors, many of whom had contributed both governmental and engineering services to the United States.

After being educated in the grade and high schools of Montclair, Mr. Owen attended Rutgers College, at New Brunswick, N. J., being graduated in 1897. In June, 1932, at the one hundred and sixty-sixth commencement of Rutgers University he received the honorary degree of Master of Science.

In 1898 Mr. Owen was employed in the tax agent's office of the Central Railroad Company of New Jersey, and he remained with that railroad throughout his entire engineering career. In August, 1899, he was transferred from the Tax Department to the chief engineer's office as a rodman, and the following November he was appointed assistant engineer, in charge of work at Mauch Chunk, Pa. In 1901 he was again transferred, this time to Jersey City, N. J., in the capacity of assistant engineer, holding that title until January, 1907, when he was made principal assistant engineer. After the death of Joseph O. Osgood, M. Am. Soc. C. E., Mr. Owen was made chief engineer on July 1, 1916, and held that position continuously until 1944.

During the first World War he assumed the duties of chief engineer of the Reading System, in addition to those of the Central Railroad of New Jersey, and in 1938 he was again officially appointed chief engineer of the Reading System and also continued his duties as chief engineer of the Jersey Central until the fall of 1943 when he retired from service on the Reading System. Such a service record illustrates, but can in no way measure, the qualities of the man and his unique characteristics.

---

[1] Memoir prepared by J. J. Yates, M. Am. Soc. C. E.

Mr. Owen was modest and unassuming and never advertised his versatile achievements. He recognized merit, and always credited a man for good qualities and effort, finding ways in which encouragement could be given. One man stated that "* * * he was the first and only man who ever took a rap for me," and others have asserted that "* * * he was a man above men."

Mr. Owen was a meticulous recorder of daily events. His diaries cover every important incident in the history of the Central Railroad of New Jersey and the Reading System, in such factual detail as to be reliable references on numerous important occasions.

Shelton Pitney and Walter P. Gardner, trustees of the Jersey Central, and William Wyer, chief executive officer, wrote of Mr. Owen in the railroad's annual report:

> "Mr. Owen was a very capable officer and a man of keen judgment and high integrity. Through his long connection with the road he knew Jersey Central history more intimately than any other officer, and his counsel and advice were of the greatest value. He served the company well and faithfully and his passing is a distinct loss to the company and to those associated with him."

Mr. Owen and his able associates completed novel construction enterprises such as harbor improvements, docks and ferries, engine terminals, railroad passenger stations, railroad and county bridges, the important Newark Bay (N. J.) Bridge with its lift and accompanying structures, the valuable reconstruction of the Jersey City train shed, and the elimination of dangerous grade crossings requiring the elevation of tracks and complete changes in the terrain of whole communities. Flood control was sponsored throughout the State of Pennsylvania, as was coastal protection in southern New Jersey.

In addition to his membership in railroad and engineering societies, Mr. Owen belonged to various philatelic and recreational groups. His opinions were frequently expressed in magazine articles, or quoted by authorities who sought his counsel. The golf course became an absorbing interest when Mr. Owen found ways to make such a desert produce first-class greens—the grower's instinct combined with engineering knowledge to produce a landscape of admirable quality. In the field of philately he achieved national prominence as an authority on the stamps of the United States. In a full-page article on Mr. Owen's death, the magazine *Stamps* stated that he "* * * was known wherever United States stamps are collected, and was probably one of the most liked and honored men in the entire fraternity," and that

> "* * * to many collectors he is probably best known for his work with the Bureau Issues Association * * *. He prepared one of the most complete records of the plate numbers used on United States stamps in existence [published by the Bureau Issues Association]. In fact, it was reported

that even the Bureau of Engraving and Printing called upon him for his record in order to correct their own."

Mr. Owen was married to Anne G. Surtees of Ottawa, Ont., Canada, in 1903. Mrs. Owen died in 1933. Mr. Owen is survived by three children, Margery S., James, and Arthur E., Jr., Sergeant, U. S. Army; and two grandchildren, James Owen, Jr., and Charles Arthur Owen. In January, 1936, Mr. Owen was married to Lillian A. Garing of New York, N. Y. Miss Garing was the former vice-chairman of the Republican organization in New York State and Queens County, New York.

Mr. Owen was elected an Associate Member of the American Society of Civil Engineers on May 3, 1905, and a Member on September 9, 1919. He became a Life Member in 1940.

ARCHIBALD E. PALEN, M. Am. Soc. C. E.[1]

Died May 1, 1944

Archibald E. Palen was born on June 1, 1882, in Niobrara, Nebr., the son of Henry Dean and Jennie (McDonald) Palen. He received his early education in Niobrara, and was graduated from the University of Nebraska at Lincoln on February 15, 1907, with the degree of Bachelor of Science in Civil Engineering.

Immediately after graduation, he became an assistant to the county engineer of Lancaster County at Lincoln. From July, 1907, to June, 1908, he worked for the Red Canyon Mining Company at Lander, Wyo., conducting preliminary canal surveys on flumes, tunnels, and siphons for a water power project. On this same project he made his initial venture into the location and construction of a mountain road—a class of work which played a prominent part in his future career.

In July, 1908, Mr. Palen sailed for the Philippine Islands and for nearly four years served as assistant engineer to the district engineer of the Highway Division of the Bureau of Public Works on the construction and maintenance of highways and other public improvements. Securing a leave of absence, from April to August, 1912, he visited Europe and studied highway location, construction, and maintenance, particularly of the mountain roads in the Swiss Alps. He then returned to the United States and was engaged on two short assignments with irrigation and mining companies in Wyoming and Colorado.

During July, 1913, he was with the U. S. Forest Service as a highway engineer in charge of federal aid construction in the national forests of Colorado, Wyoming, and South Dakota. In June, 1914, Mr. Palen was transferred to the Bureau of Public Roads, thereby becoming one of the pioneer engineers of this organization (later the U. S. Public Roads Administration). As assistant to the district engineer of the Public Roads Administration, he handled, very successfully, forest highway location, construction, and maintenance in the Rocky Mountain States of Colorado, Wyoming, and New Mexico and in the Black Hills region of South Dakota during the period when the early mountain trails were being developed and transformed into higher type mountain highways.

---

[1] Memoir prepared by a Committee of the Colorado Section consisting of Jesse E. Williams, Assoc. M. Am. Soc. C. E., and Clyde E. Learned and Carl A. Gould, Members, Am. Soc. C. E.

On April 1, 1929, Mr. Palen was appointed acting district engineer of the Public Roads Administration at Denver, Colo., in charge of federal aid, forest highway, and national park major road construction. On February 1, 1933, he was transferred to the St. Paul, Minn., office as district engineer of the Public Roads Administration, handling all federal aid highway activities in the states of Minnesota, Wisconsin, North Dakota, and South Dakota, until his death.

Probably Mr. Palen's most outstanding characteristic that many of his associates will remember was his balanced and cheerful disposition, even under the most trying circumstances. In all his dealings Mr. Palen had a keen sense of responsibility, and he was a man of unimpeachable integrity. His professional ethics were especially high, with the result that he was admired and respected by those with whom he came in contact. He was very loyal to his organization, had the ability to select good men and train them, and was very deliberate in studying and arriving at fair and just decisions.

Mr. Palen was an active member of the Christian Science Church and was a member of the Masonic Fraternity.

On July 16, 1910, in Manila, Philippine Islands, he was married to Edna E. Chidester. He is survived by his widow and two daughters, Katherine (Mrs. B. K. Atkins) and Mary.

Mr. Palen was elected an Associate Member of the American Society of Civil Engineers on January 17, 1916, and a Member on April 26, 1921.

THEODORE BISSELL PARKER, M. Am. Soc. C. E.[1]

Died April 27, 1944

In the untimely death of Theodore Bissell Parker the engineering profession suffered the loss of an outstanding exponent of many of the highest traits of his profession. Forceful and energetic by nature, with a comprehensive grasp of technical matters, he possessed a combination of the qualities of leadership, executive ability, and technical skill which peculiarly fitted him for his career as an administrative engineer.

Descended from several generations of New England stock, Theodore Bissell Parker was born in Roxbury, Mass., on August 20, 1889, the son of Franklin Wells and Sarah (Bissell) Parker. Although his father died when

---

[1] Memoir prepared by C. E. Blee and R. T. Colburn, Members, Am. Soc. C. E., and Sherman M. Woodward, Hon. M. Am. Soc. C. E.

Theodore was but ninteen, his mother was determined that he should complete his college course and prepare for a profession. After graduation from high school in Wellesley, Mass., in 1907, he entered the Massachusetts Institute of Technology (M. I. T.) at Boston, and was graduated in June, 1911, with the degree of Bachelor of Science. He was elected to membership in the historic Alpha Theta Chapter of Sigma Chi fraternity.

It was not by mere chance that Mr. Parker was elected first marshal of his class, for, throughout his school life, he was recognized as a leader whose integrity was unusual, whose judgment was sound, and whose friendship was available to all. While in school, in addition to his ability as an outstanding leader, he was noted for his all-around athletic prowess and his inherent sense of fairness. He was fond of sports—golf, tennis, squash, basketball, and baseball. Excelling in most games, he was above the average in all.

After graduation, Mr. Parker was an assistant in the Department of Civil Engineering at M. I. T. for a year and then joined the staff of the late H. C. Keith, M. Am. Soc. C. E., consulting engineer of New York, N. Y., as draftsman and computer on highway and railroad bridges. Mr. Parker began to specialize in hydroelectric development in 1912 when he was employed as assistant hydraulic engineer by the Utah Power and Light Company. Hydroelectric projects remained his principal professional interest thereafter. While with the Utah Company, Mr. Parker was connected with the construction of new power developments on the Bear River in Idaho and the reconstruction of the existing hydroelectric system in Utah.

Then, the United States entered World War I in 1917, and he joined the Army as First Lieutenant, later becoming Captain and commander of Company D of the Twenty-Sixth Engineers in service overseas. After returning from abroad, in April, 1919, Mr. Parker joined the Electric Bond and Share Company as assistant hydraulic engineer, engaged in investigations and reports regarding power sites on the Platte, Loup, and Niobrara rivers in Nebraska, and on the Susquehanna, Delaware, and Lehigh rivers in Pennsylvania. In October, 1920, Mr. Parker again entered the Army, serving as Captain in the Corps of Engineers until November, 1922. This tour of duty included a year of service with troops and a year at the Army Engineer School, in Fort Humphreys, Va., from which he was graduated in 1922.

In December, 1922, he resumed civilian life as an hydraulic engineer with the Stone and Webster Engineering Corporation. In this capacity he was active on several important hydroelectric developments, including the Bartlett's Ferry Project near Columbus, Ga., and the Rock Island development on the Columbia River in Washington, serving as project engineer in charge of design on both of these projects.

In the spring of 1933 Mr. Parker, as a reserve officer, attended the U. S. Army Command and General Staff School at Fort Leavenworth, Kans., where he received the commission of Lieutenant Colonel in the Corps of Engineers Reserve. In August, 1933, he became a member of the engineering staff of the Federal Emergency Administration of Public Works, serving, successively, as engineer examiner, state engineer, and acting state director for Massachusetts.

Colonel Parker joined the Tennessee Valley Authority (TVA) in November, 1935, as chief construction engineer, responsible for the general supervision of lock, dam, powerhouse, and appurtenant construction work. At this time the Norris and Wheeler projects were under construction; the Pickwick Landing project had just been started; and the Chickamauga, Guntersville, and Hiwassee projects had only been authorized. In May, 1938, Colonel Parker was named chief engineer, in charge of all engineering and construction work for the entire Tennessee River development program—an unprecedented system of projects for water control in the Tennessee Valley.

As chief engineer of TVA, he had general responsibility for the planning, design, and construction of the Kentucky, Watts Bar, Fort Loudoun, Cherokee, Douglas, Apalachia, Ocoee, Nottely, Chatuge, and Fontana dams and the Watts Bar Steam Plant. Substantially all the work on these projects was done by force account. The greatest number of engineers employed at any one time was about 2,500, and the maximum total number of employees in the Engineering Department and the Construction Department was about 29,000.

Colonel Parker was devoted to the promise and completion of his work in the Tennessee Valley, interested in, and proud of, the accomplishments of his men. Some two years before the completion of Douglas Dam, an urgently needed war project, his alma mater, M. I. T., called him. He wanted to go—to return to the scene of his youth and to teach—but he delayed his acceptance until Douglas Dam was finished. Then he felt free to go—and not before. Thus, in June, 1943, he left the Tennessee Valley and returned to Massachusetts to become head of the Department of Civil and Sanitary Engineering at M. I. T.

The high esteem the members of the TVA Engineering Department and the Construction Department held for Professor Parker is best indicated by the wording of a scroll presented to him at the time of his leaving:

> "We, members of the TVA engineering and construction staff, desire to express our sincere appreciation of the privilege of having been able to serve under your intelligent and able leadership. We bid you Godspeed in your new duties and want to assure you of our intention to carry on the high ideals of service and the standards of practice you have inculcated and left with us here in the Authority. We view with regret TVA's loss and look forward to sharing M. I. T.'s gain."

Professor Parker's professional career can be measured only in part by the many notable engineering projects with which he was associated. The full measure of his success must include the encouragement he so generously gave the younger members of the profession, the friendship he tendered his associates, and the honor and esteem in which his colleagues hold his memory.

The engineering problems involved in the development of the natural resources of foreign countries devastated by war were very interesting to him. Professor Parker believed that these problems could best be coped with, and ultimately solved, by competent, loyal engineers of the countries themselves. In his characteristic, straightforward manner he was taking steps to help train these men.

He was active in the affairs of local and national engineering organizations. At one time he was a member of the Boston Society of Civil Engineers, from which organization he, together with the late Harry A. Hageman, received the Desmond Fitzgerald Medal for a joint paper on the Bartlett's Ferry Project,[2] which was considered the most outstanding paper of 1926. Professor Parker also was the author of numerous other papers.[3,4,5,6,7] He was a member of the Water Resources Committee of the National Resources Planning Board and a director of the Society of American Military Engineers.

He participated in the activities of the Tennessee Valley Section of the Society as well as in the activities of the Socitey as a whole. His last trip, undertaken even while ill, was to attend the Society's Annual Meeting in January, 1944, at which time he presented a paper on "Major Hydraulic Objectives of the Tennessee Valley Authority."

To his associates Professor Parker was an intense, dynamic personality; an outstanding leader; an engineer of wide experience, prompt in making decisions and always willing to assume responsibility; and a loyal friend who at all times commanded confidence and respect. With a touch of shyness and an extreme modesty, in spite of pressing demands on his time, he remained ever sensitive to the trials and efforts of his associates; and in his own quiet, friendly manner, either by a visit or a personal note, he made other men aware of his interest in their welfare. He was never too preoccupied to greet and encourage the younger members of the profession. His strength of character, his sincerity of purpose, and his desire to serve his fellow men influenced the lives of innumerable associates. Through them his ideals live on.

As a tangible and lasting evidence of esteem, his friends and associates have created an education fund in his memory, known as The Theodore B. Parker Memorial Fund. On the occasion of initiating this endeavor, one of the speakers representing the management of the TVA aptly stated,

> "Colonel Parker's personality, his engineering competence, and his administrative sense are written forever into the TVA and the Tennessee Valley. The attribute he possessed of putting first things first made him a bold engineer and a sometimes impatient administrator. He tempered boldness and courage with a commendable quality of New England caution. * * * 'Make sure of what you're doing—then go ahead' was a characteristic epigram in his discussions of a program."

On May 10, 1913, Professor Parker was married to Estelle Peabody of Wellesley. He is survived by his widow; his mother; and two children,

Franklin P. Parker (Major, Corps of Engineers, U. S. Army) and Nancy Parker.

Professor Parker was elected an Associate Member of the American Society of Civil Engineers on August 9, 1920, and a Member on March 30, 1931.

GEORGE WELLINGTON PICKELS, M. Am. Soc. C. E.[1]

Died December 2, 1944

George Wellington Pickels, the son of George Wellington Pickels and Minnie (Parrish) Pickels, was born on September 5, 1883, in Richmond, Ky., where he grew to manhood. In 1904 he received the degree of Bachelor of Civil Engineering from the University of Kentucky at Lexington and in 1911 was awarded the professional degree of Civil Engineer by the University of Illinois at Urbana.

He began his professional career as resident engineer on the construction of the Murrayville (Ill.) cutoff of the Chicago and Alton Railroad Company. In the fall of 1907 he accepted a position as instructor in civil engineering at the University of Illinois; and, during his thirty-seven years of service at the University, distinguished himself as a teacher, author, and investigator in the fields of hydrology, land drainage, and flood control, and became a recognized authority on those subjects. When he died, he held the rank of professor of civil engineering in the fields of drainage and flood control engineering.

During World War I, Professor Pickels served as head of the Department of Aids to Flight in the United States School of Military Aeronautics at the University with the rank of First Lieutenant. Following the war, he took an active part in many investigations of the problems of land drainage and flood control in Illinois and for several summers he served as drainage engineer for the Illinois State Geological Survey.

The intimate knowledge of the hydrological and other characteristics of the state gained in this work made Professor Pickels unusually adept in selecting possible sites for reservoirs and lakes in various parts of the state. He lived to see the consummation of a major project of this kind which he outlined. This is the Crab Orchard Dam, built by the U. S. Resettlement Administration a few miles east of Carbondale, Ill., on a tributary of the Big Muddy River, creating the largest artificial body of water in the state with immediate and important economic results and great future potentialities.

Professor Pickels' report on this project formed the major part of a document entitled "A Reconnaissance Report on the Basin of the Big Muddy River" issued jointly by the University, the Illinois State Geological Survey, the Illinois State Natural History Survey, and the Illinois State Water Survey in 1935. He contributed a significant section to a similar but more elaborate document entitled "The Physical, Social, and Economic Aspects of the Valley of the Kaskaskia River" issued in 1937 by the same agencies. (These two documents were not printed but issued in rather large mimeographed editions. They were prepared for specific purposes and are mentioned because they have been of immense value in the State of Illinois and because of Professor Pickels' outstanding contributions to them.)

---

[1] Memoir prepared by C. C. Wiley, M. Am. Soc. C. E.

His other writings consisted of technical articles, reports, bulletins, and textbooks. As coauthor with F. B. Leonard, he prepared a bulletin on the "Engineering and Legal Aspects of Land Drainage in Illinois,"[2] published by the State Geological Survey in 1921. He also wrote two bulletins for the University of Illinois Engineering Experiment Station on "Run-Off Investigations in Central Illinois"[3] and "Magnitude and Frequency of Floods on Illinois Streams."[4] "A Textbook on Railroad Surveying"[5] and a larger and more complete volume on "Route Surveying"[6] were prepared in collaboration with the writer. Perhaps Professor Pickels' outstanding contribution to engineering literature was his book entitled "Drainage and Flood-Control Engineering."[7]

In addition to serving on Society committees, he was a charter member of the Central Illinois Section and later served as its Secretary-Treasurer, Vice-President, and President. He was a member and a past-president of the Illinois Society of Engineers and belonged to the Society for the Promotion of Engineering Education, the American Geophysical Union, and the American Water Works Association. He was also founder and chairman of the drainage conferences held at the University of Illinois from 1916 to 1921, inclusive.

Professor Pickels possessed a most engaging personality, combining a quiet dignity with a ready wit and a warm and genial disposition which endeared him to everyone. He was keen, competent, and meticulous in his work and tolerant and cooperative with others. It was both pleasant and stimulating to associate and to work with him. He enjoyed being with students and possessed to a high degree the qualities of a good teacher. As a result he was held in high regard by his students as well as by his colleagues. He was interested in civic affairs and served a four-year term as a member of the Urbana City Council.

On May 16, 1907, in Winchester, Ky., he was married to Elizabeth S. Robinson. Professor Pickels is survived by his widow; a daughter, Elizabeth C. Pickels; and a son, George Wellington Pickels—fourth successive bearer of the name.

---

[7] "Drainage and Flood-Control Engineering," by G. W. Pickels, 2d Ed., McGraw-Hill Book Co., Inc., New York, N. Y., 1941.

In the death of Professor Pickels the profession lost a valuable member; the University, one of its ablest men; the community, an outstanding citizen; and his associates, a beloved friend.

Professor Pickels was elected a Member of the American Society of Civil Engineers on May 19, 1924.

JOHN RICHARDS GRAY PILL, M. Am. Soc. C. E.[1]

Died January 29, 1944

John Richards Gray Pill was born on July 6, 1866, in the village of Perranporth, Cornwall, England, the son of William and Mary (Gray) Pill. For generations, his paternal forebears had been associated with the tin and copper mining industry of England. His mother was Scotch and a daughter of an officer of the British Army.

He acquired his early education at Truro Academy in Truro, Cornwall, England, and at the National School, near Toulon, France. He won scholastic honors at both schools. His parents moved from France to St. Johns, Newfoundland, where he completed his engineering education at Methodist College (of St. Johns) receiving the degree of Civil Engineer.

From 1885 to 1887, Mr. Pill was in the employ of the Engineering Department of the Newfoundland government and served as assistant construction engineer on the Placentia Railway Project. Later, he headed an expedition sent by the Newfoundland government to prospect for mineral deposits in Labrador. The party spent more than a year in this search, and secured many valuable data on these resources. For this work he was highly commended by his superiors.

In 1888 he entered private practice with Payne and Howell, Civil Engineers of Knoxville, Tenn. In 1891 he was employed as chief assistant engineer on the Knoxville and West Knoxville sewer systems. In 1894 Mr. Pill became assistant engineer, Construction Division of the Southern Railway Company, and was assigned to the offices at Knoxville and Chattanooga, Tenn., and Birmingham, Ala.

In January, 1901, he resigned his position with the Southern Railway Company and was named chief engineer of the Galloway Coal Company of Carbon Hill, Ala. Later in 1901 he was promoted to general superintendent and was placed in charge of direction and development of extensive coal mining operations in Walker County, Alabama. In 1907, he also became vice-president and general manager of the Choctaw Coal and Mining Company and assumed the additional duty of directing its mining operations.

Early in 1909, Mr. Pill was appointed president and general manager of the Birmingham Fuel Company with the duty of opening and developing mining operations at Townley, Ala. By 1912 the output of these mines was 230,000 tons of coal annually. In March, 1912, the Birmingham Fuel Company acquired the holdings of the Corona Coal and Iron Company in Walker County. The properties were merged and operated as the Corona Coal and Iron Company. Mr. Pill was made general manager of the new company and moved with his family to Corona, Ala. He managed eight mines for the company and increased the output more than 1,000,000 tons annually. During his active mining career, he was in responsible charge of engineering and construction work from ground breaking to complete operation of ten or more mines.

---

[1] Memoir prepared by a Committee of the Alabama Section consisting of W. G. McConnel and C. A. Wilmore, Members, Am. Soc. C. E.

Mr. Pill was most successful in directing and handling men. Always solicitous as to their safety, he did not ask employees to begin dangerous operations until he had led the way. He provided accident insurance, medical care, and early established a system to provide for the welfare of the men and their families.

During World War I, Mr. Pill served, at personal sacrifice, with the Engineers Committee of the United States Fuel Administration in Washington, D. C. He was cited for distinguished service by the administration.

In 1920 Mr. Pill opened consulting offices in Birmingham. He acquired an interest in and was vice-president of the Southern Mineral Land Company. His practice included extensive service to the State of Alabama and various mining companies, as consultant on mineral properties in the state. He also served as land trustee for Alabama College, Montevallo, Ala. —an association which he thoroughly enjoyed.

He entered the employ of the Woodward Iron Company of Woodward, Ala., in 1927, as manager of the Land Department and continued in that capacity until his death. To this work, he brought a wide knowledge of the coal and iron industry and of mineral property values. His services were of such value and quality as to merit the praise of fellow officials and the respect of employees. No other tour of duty afforded him more satisfaction than his service with the Woodward Iron Company.

Throughout his long residence in Alabama, Mr. Pill studied the state's mineral lands and deposits. By personal exploration (often on foot) and the study of books, technical articles, and papers, he gained a vast store of information. Mr. Pill loved the outdoors, was almost completely free of illness of any kind, and was very active until he was hospitalized before his death. His recreations were fishing, hunting, checkers, and chess at which he was very adept. He was an inveterate reader—at least four hours daily—and a constant student.

Although he was quiet, reserved, almost to the point of shyness but with a keen wit, his friends were limited only by his acquaintance. He was a man who was seen and known too little by too few. He loved his home, and the family was one of mutual devotion.

Mr. Pill was a fellow of the Royal Society of Arts (Great Britain). He belonged to the American Institute of Mining and Metallurgical Engineers, the Rocky Mountain Club (New York, N. Y.), and the Episcopal Church.

On October 31, 1894, he was married at Knoxville to Katherine Rant, who died in July, 1943. One son, Donald Rant Pill, died in 1914. Mr. Pill is survived by one daughter, Mary Louise (Mrs. W. S. Green), and one son, Howard Edgar Pill.

Mr. Pill was elected an Associate Member of the American Society of Civil Engineers on February 7, 1906, and a Member on March 4, 1913.

JAMES CHARLES PINNEY, M. Am. Soc. C. E.[1]

Died December 2, 1944

James Charles Pinney was born at Sturgeon Bay, Wis., on October 17, 1882. He was the son of James C. and Abigail (Hannan) Pinney. He was graduated from Fargo College at Fargo, N. Dak., in 1905, receiving the degree of Bachelor of Arts in Mathematics. In 1910 he received the degree of Civil Engineer in structures and hydraulics from the University of Wisconsin at Madison.

After graduation from Fargo College, Mr. Pinney spent five years in various field positions: Chief of party for the reconstruction of the main line of the Great Northern Railway Company; assistant engineer in charge of field party on maintenance and right of way for the Minneapolis and St. Louis Railroad Company; assistant city engineer of Fargo on office and field work for the city's sewer and water extension program; and finally county surveyor for Door County, Wisconsin.

In 1910 he accepted an assistant professorship at Marquette University in Milwaukee, Wis., where he taught courses in structural engineering and in material testing. During his stay at Marquette University he acted as a consultant for the City of Milwaukee; and in 1912 he became superintendent of bridges and public buildings, in charge of the design and construction and repairs and maintenance of all bridges, public buildings, and waterfront structures, costing more than one million dollars. Having completed most of the construction planned by the city, Mr. Pinney returned to Marquette University in 1917 as dean of the College of Applied Science and Engineering where he established a cooperative engineering course that permitted students to obtain practical experience while attending the university. He was retained as a private consultant by the City of Milwaukee on various engineering work—including the design of the North Avenue Viaduct, Scott Street Bridge at Fond du Lac, Wis., and the car ferry terminal for the Milwaukee Association of Commerce.

In 1925 Mr. Pinney entered private consulting practice and became a member of the firm of Lee County Engineering Company at Fort Myers, Fla. He specialized in municipal engineering and surveying, and worked on the subdivisions of Riverside, Twin Palms, York Manor, and Orangewood, all at Fort Myers. He owned a local orange grove which was his pride and joy. After ten years in private practice, he entered the service of the federal government as chief of party for the U. S. Biological Survey. He then was employed by the U. S. Coast and Geodetic Survey, and in 1939 he became engineer in the Dams Division for the Bureau of Reclamation, U. S. Department of the Interior, in Denver, Colo., remaining until his death.

---

[1] Memoir prepared by Dirk A. Dedel, Assoc. M. Am. Soc. C. E.

Mr. Pinney was a quiet, hard-working man who won the esteem of his associates by his profound knowledge of engineering principles and his high regard for engineering ethics. He belonged to the Engineering Society of Wisconsin (past-president and honorary member), the Society for the Promotion of Engineering Education, the American Railway Engineering Association, the Florida Engineering Society, and the Engineers and Architects Club of Fort Myers.

In March, 1936, at Galveston, Tex., he was married to Mabel Stiff. He is survived by his widow.

Mr. Pinney was elected a Member of the American Society of Civil Engineers on April 16, 1918.

FRED ASHLEY PNEUMAN, M. Am. Soc. C. E.[1]

DIED NOVEMBER 30, 1942

Fred Ashley Pneuman was born in Cortland, N. Y., on November 12, 1899. At an early age he moved with his parents to Georgetown, Colo., where he received his primary education in the public schools. In 1912, when the family moved to a ranch near Denver, Colo., he continued his studies at the North Denver High School. After graduation, he entered the University of Colorado at Boulder, receiving the degree of Bachelor of Science in Civil Engineering in 1922.

Shortly after his graduation from college, Mr. Pneuman entered the employ of the American Bridge Company at Gary, Ind., as a structural draftsman and remained continuously with that company until his death. During this period he was employed in various engineering capacities. From 1922 to 1929, he worked at the company's Gary plant as a draftsman and checker on structural steel for office buildings, mill buildings, and bridges of both the fixed and movable types. During this period Mr. Pneuman developed a particular interest in the mechanical features of movable bridges, and, because of his aptitude for this type of work and his fertile imagination in developing new ideas, he was transferred to the designing office of the American Bridge Company at Chicago, Ill., in July, 1929. In this office, he was employed for four years as a designer on various types of steel structures, particularly movable bridges and operating machinery. He assisted in the design of the mechanical features for the vertical lift span in the bridge of the Missouri, Kansas and Texas Railway Company over the Missouri River at Boonville, Mo., and for the vertical lift bridge of the Elgin, Joliet and Eastern Railway Company over the Illinois River at Joliet, Ill. He also designed the machinery for three large bascule bridges.

---

[1] Memoir prepared by T. A. Jordan, A. S. Marvin, and George W. Serat, Members, Am. Soc. C. E.

Late in 1932 the contract for the construction of the San Francisco-Oakland Bay (Calif.) Bridge was awarded to the American Bridge Company, and in January, 1933, Mr. Pneuman was transferred to the Erecting Department to assist in the development of construction plans and in the design of equipment required for the erection of this unusual structure. By January, 1935, the work on the bridge was progressing satisfactorily, and the erectors were ready to place the suspension spans. At this time Mr. Pneuman was transferred to San Francisco where, during the next year and a half, he was largely responsible for the continuous operation of the cable spinning equipment. During this period, he conceived and developed many improvements in the method of spinning cable for suspension bridges, and several of his innovations have since been adopted as standard practice.

After completion of this assignment in 1936, Mr. Pneuman was transferred to the New York (N. Y.) office of the American Bridge Company to take charge of the engineering work in connection with the erection procedure and equipment for the Marine-Parkway Bridge—a vertical lift structure, in New York. His next assignment was as resident engineer on the Bronx-Whitestone Bridge project, also in New York City. This bridge—a suspension bridge of unusual proportions and design—gave Mr. Pneuman an excellent opportunity to apply the knowledge and experience he had gained on the San Francisco-Oakland Bay Bridge. He planned the erection and also designed the erecting equipment.

Upon the completion of the Bronx-Whitestone Bridge in 1939, Mr. Pneuman returned to the designing office of the American Bridge Company at Chicago where he remained until his death. During this period he was given several important engineering assignments, including the design of a bascule bridge for the Southern Pacific Company at Beaumont, Tex., and the erection plans for the Kettle Falls Bridge in the State of Washington.

Mr. Pneuman was an active member of the Masonic Lodge and was also interested in all forms of athletics. His particular hobby, however, was amateur photography, and he acquired considerable skill in taking both still and motion pictures. His motion pictures of field work have been of considerable value and interest to his engineering associates. He possessed a magnetic personality which endeared him to all who knew him, particularly to the younger engineers who frequently received his patient assistance and guidance.

In 1923 he was married to Mildred Young, who, together with one son, Frederick, survives him. A daughter, Shirley, died in 1939.

Mr. Pneuman was elected a Member of the American Society of Civil Engineers on July 10, 1940.

CORYDON TYLER PURDY, M. Am. Soc. C. E.[1]

DIED DECEMBER 25, 1944

Corydon Tyler Purdy, the son of Samuel J. and Emma Jane (Tyler) Purdy, was born on May 17, 1859, in Wisconsin Rapids, Wis. He was of English ancestry, dating back to the fourteenth century.

When he was still a small boy, a new Howe-truss timber bridge was built across the Wisconsin River in the lower part of Wisconsin Rapids. Mr. Purdy in later years told of his absorbed interest in the building of this bridge. He spent as much time watching the workmen as his parents would permit. Apparently greatly impressed, he announced then and there that he would become an engineer when he grew to manhood. He never changed his mind, nor his determination to carry out his plans.

He received his elementary and high school education in Wisconsin Rapids and then attended the University of Wisconsin at Madison. Because of difficulties with his eyesight, he was forced to interrupt his studies at the university for several years. During this time, he was employed periodically on railroad survey work and also as a draftsman.

In 1882 he was appointed assistant engineer by the Chicago, Milwaukee, St. Paul and Pacific Railroad Company, in charge of field surveys for a new railroad entrance to Chicago, Ill., through Evanston, Ill.

In 1883 he returned to the University of Wisconsin to complete his course, being graduated in 1885 with the degree of Civil Engineer. Three months before his graduation, he was elected city engineer of Eau Claire, Wis. He resigned from this position in the fall of 1887 and for the next two years worked as a material inspector in Pittsburgh, Pa., and also in the Engineering Department of the Keystone Bridge Works.

In 1889 Mr. Purdy opened his first office in Chicago as a consulting engineer on the design of bridges. Chicago at this time was experiencing considerable expansion in building construction and the attention of real estate owners, architects, and contractors was concentrated on the problem of erecting tall structures on the valuable property in the business sections of the city. In a general way, the construction of higher buildings followed the lines of earlier construction of relatively low buildings in that the important vertical supports were still the masonry exterior walls and interior piers. Cast-iron columns and iron floor beams were beginning to be used extensively in the interior construction of buildings, but masonry was being strained to support taller buildings. As an example, the Monadnock Building, seventeen stories high and probably one of the highest masonry commercial structures ever built, had walls seven feet thick on the ground story.

Mr. Purdy observed and studied these conditions and began to visualize the enormous possibilities in the adaptation of steel supporting members for building construction. This theory, given more and more attention during the next few months, caused him to revise the plans he had prepared for his future as an engineer. He decided to turn from bridge construction and bend every effort to develop a field of structural engineering in building construction, an endeavor for which he was already equipped by education and training. He soon became one of a group of men intent on inaugurating a new form of building construction based on the use of a structural steel frame. In his own words, "We were not discovering, nor inventing; we were evolving." The evolution became very rapid. Before the Columbian Exposition opened in 1893, buildings of unprecedented height had been designed and erected and the tremendous advantages of steel frame construction were fully demonstrated.

---

[1] Memoir prepared by P. J. Reidy, Assoc. M. Am. Soc. C. E.

During this period, with a member of his office staff, Lightner Henderson, Mr. Purdy formed the partnership of Purdy and Henderson. Many important features of steel construction in buildings, methods of calculations, and standard details were originated by this partnership, an association which endured until Mr. Henderson's death in 1916.

The Columbian Exposition had given considerable publicity to steel frames in high buildings and, as a result, Mr. Purdy was asked to lecture before engineers and engineering students at Boston, Mass., and at Cornell University in Ithaca, N. Y.

In 1894 Mr. Purdy decided that the field of structural design, which had been developed largely through his efforts, would be particularly adaptable to New York, N. Y., although conditions at that time, in the opinion of most of his Chicago associates, made it difficult to prove the value of such engineering service to the owner, architect, or builder. However, Mr. Purdy proceeded with his intention to open a New York office and, after almost a year of patient study and introductory effort, he obtained his first important commission—namely, the design of the foundations and superstructure of the Waldorf-Astoria Hotel. Thereafter, Mr. Purdy remained in the New York office which, with the increase in the volume and importance of the business, became the headquarters of Purdy and Henderson in 1901, when the partnership was incorporated. Branch offices were subsequently opened in Boston, Mass.; Montreal, Que., Canada; Seattle, Wash.; and Vancouver, B. C., Canada.

In 1896 George A. Fuller, a prominent contractor of Chicago, requested Mr. Purdy to establish a New York office for his firm. For the following year Mr. Purdy had charge of Mr. Fuller's business while his partner, Mr. Henderson, managed the New York office of Purdy and Henderson. In 1897 Mr. Purdy resigned from the Fuller organization and resumed the management of Purdy and Henderson.

When the United States Realty and Construction Company was organized in 1898, it was the largest combination of realty and construction interests at that time. Mr. Purdy was requested to join the organization as chief engineer; but, in accordance with his wish to remain effective head of his own business, an arrangement was made to retain Purdy and Henderson as structural consultants for all the Realty Company's activities.

In 1900 Mr. Purdy prepared the provisions under which the ownership of the site of the proposed New York Times Building was transferred to the New York Times Company. This building at Times Square, New York City, is directly over the subway, with four tracks running through the building above the pressroom in the subbasement. Some years later, Mr. Purdy prepared a paper for the Institute of Engineers of Great Britain containing an analysis of structural vibration in buildings, for which he was awarded the Telford Premium. At the request of the United States Government, Mr. Purdy organized and supervised the preparation of an exhibit for the Paris (France) World's Fair of 1900 to show the details and methods of modern steel frame construction of buildings, as well as all the other features of a multistory office building. A building then under construction in New York was used as a model.

In 1900 Mr. Purdy went to Cuba and, as a result of his survey of prospects, opened an office in Havana. The subsequent rapid development of Cuba brought a large volume of business to this office. Although originally the Havana office was to be an engineering office similar to those in the United States, it soon became evident that this idea was not adaptable to general business practice in Cuba. To continue the office, it was found necessary to enter the construction field. In turn, a subsidiary company had to be organized for the importation and distribution of building materials and equipment. The company formed for this purpose was the Purdy and Henderson Trading Company, which later specialized in general importing. One of the firm's Cuban activities and interests was the construction of branch banks for the Royal Bank of Canada in all parts of Cuba and on some of the other islands in the Caribbean area. This arrangement worked out so well that, at the request of the Royal Bank, the Purdy and Henderson Company, Inc., was asked to build branch banks throughout Canada. To accomplish this, the Purdy and Henderson Company, Ltd., was organized in 1909. Representative of the construction in Cuba were the Cuban Capital, Banco Nacional de Cuba, Centro Gallego, Centro Asturiano, and the Nacional Hotel. For a time, a branch of the company was operated in Puerto Rico.

In 1905, and again in 1908, Mr. Purdy visited England and made extensive surveys of building construction design and methods. While there, he delivered several lectures on the construction procedures being developed in the United States and had a long interview, during the 1908 trip, with Sir Guilford Molesworth, then president of the Institute of Engineers of Great Britain, who subsequently nominated Mr. Purdy for membership in the institute.

After the Baltimore (Md.) fire in 1904, Mr. Purdy was retained by the Hon. E. Clay Timanus, then Mayor of Baltimore, as consultant to the commission created to revise the building code.

Mr. Purdy resigned as president of the Purdy and Henderson Company, Inc., in 1917, but continued his active association with the firm as chairman of the board of directors, a position he filled until his death. During his years as active head of his company, he was responsible for the structural design of many prominent buildings. Illustrative of the range of the firm's accomplishments are the following: Waldorf-Astoria Hotel, New York Times Building, Flatiron Building, New York Municipal Building, R. H. Macy store, Pennsylvania Station concourse, Hudson Terminal, and New York Hippodrome in New York, N. Y.; Custom House Tower in Boston, Mass.; Cook County Court House and McCormick Building in Chicago, Ill.; Willard Hotel in Washington, D. C.; B. F. Goodrich Plant in Akron, Ohio; Capwell store in Oakland, Calif.; Royal Bank Building in Toronto, Ont., Canada; and Ocean Terminal Station in Halifax, N. S., Canada.

In later years Mr. Purdy devoted much time to the operation of his farm near Monroe, Orange County, N. Y. This property had been owned by his ancestors for about two hundred years. The original deed, still in existence, was written on two sheets of parchment in 1734. Another interest to which he devoted much time and effort, particularly after 1920, was the welfare of youth, first locally in Orange County and then in New York City. He later became a director of the National Child Welfare Association.

In his relationships with his associates and employees, Mr. Purdy always showed keen interest in their advancement, both technically and financially, if they were trustworthy and dependable. Most of the men who, in later years, directed the affairs of Purdy and Henderson Company, Inc., were encouraged in their efforts by Mr. Purdy's willing recognition of their individual merits. He was fond of quoting a part of an essay which he learned to speak as a schoolboy in Wisconsin Rapids:

> "Opportunity has hair in front, behind he is bald. If you seize him by the forelock you may hold him, but if suffered to escape, not Jupiter himself can catch him again."

His own career is an example of the road to a successful and full life: His early determination to be an engineer; his single-minded efforts to obtain the education and training necessary to equip him for his vocation; his untiring work to succeed as an engineer; his willingness to share success with his associates; and his ability to act promptly when opportunity presented itself.

Mr. Purdy was a member of the Western Society of Engineers, the Institute of Engineers of Great Britain, the Engineers' Club of New York, the New York State Engineering Society, the Arctic Club of Seattle, and the Civitan Club of New York.

In 1890 he was married to Eugenia Cushing of Turner, Me., who died within a year. In 1892, in Columbus, Ohio, Mr. Purdy was married to Rose E. Morse. He is survived by his widow; a son, Corydon P. Purdy; and a grandson, Corydon P. T. Purdy.

Mr. Purdy was elected a Junior of the American Society of Civil Engineers on February 2, 1887, and a Member on December 6, 1893.

IRA LAWRENCE PYLE, M. Am. Soc. C. E.[1]

DIED MAY 1, 1944

Ira Lawrence Pyle was born in Philadelphia, Pa., on March 27, 1877, and was educated in private schools in that city. The son of Abram Pyle and Ella (Sweeney) Pyle, he was of Irish and Dutch ancestry and combined the imagination and keenness of the former race with the thoroughness and patience of the latter race.

Early evincing a preference for the profession of engineering, Mr. Pyle began his career in 1901 in the drafting room of the Pennsylvania Railroad Company in Philadelphia. At the suggestion of the late Col. Joseph U. Crawford, engineer of branch lines of the Pennsylvania Railroad Company, that the coal and timber lands of southern West Virginia, then being developed, offered especially attractive opportunities for ambitious young engineers, Mr. Pyle secured a job with a field party making land surveys in West Virginia, doing both instrument and drafting work. In 1902 he transferred to the Chesapeake and Ohio Railway Company. At that time, this line was beginning to reach out into the rich coal and timber fields of southern West Virginia. During his subsequent career, Mr. Pyle was identified with the Chesapeake and Ohio Railway Company.

From 1902 to 1922, Mr. Pyle advanced from draftsman with a field party, to levelman and transitman, and finally to resident engineer and assistant engineer in charge of heavy construction. During these two decades his promotions were slow, but it was characteristic of him that he mastered all the details of his work and prepared himself for the more important duties he was later to assume. On January 1, 1923, he was appointed assistant chief engineer. Following the death of C. W. Johns,[2] M. Am. Soc. C. E., chief engineer of the company, on September 18, 1939, Mr. Pyle was appointed chief engineer, remaining in this capacity until his death.

During the 20-yr period from 1923 to 1943, when Mr. Pyle was assistant chief engineer and then chief engineer, the total investment of the Chesapeake and Ohio Railway Company in road and equipment more than doubled. All classes of physical property were included in this tremendous increase, and improvements were made and facilities added to every division of the system from Hampton Roads, Va., to the Great Lakes. Millions of dollars were spent annually, even during the economic depression, on the construction of new main lines and branches; on the construction and improvement of yards and terminal facilities; on the elimination, enlargement, and improvement of tunnels; on the strengthening and renewal of bridges; and on the construction of wharfs and docks. In addition, new engine houses and shops for heavier motive power and equipment were provided as were many other facilities and improvements that have played an important part in making the

---

[1] Memoir prepared by Crosby Miller, Assoc. M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 105 (1940), p. 1866.

Chesapeake and Ohio Railway Company one of the great coal carrying railroads of the United States.

Mr. Pyle, with the assistance of capable associates, planned and executed the many important projects entrusted to him and retained his interest and enthusiasm for his work until his death.

Mr. Pyle was a man of wide interests and varied but quiet tastes. He was keenly interested in fine horses and dogs and delighted in good music and books and in a well-arranged garden. A man of broad sympathies, he had a deeply religious nature. A member of the Overbrook Presbyterian Church of Richmond, Va., for a quarter of a century, he was elected a representative from the presbytery to the general assembly and was regarded as a leader in the affairs of the Presbyterian Church in the South.

On July 1, 1903, he was married to Bessie Boozer of Philadelphia. Mr. Pyle is survived by his widow.

Mr. Pyle was elected a Member of the American Society of Civil Engineers on December 9, 1940.

MILTON ALLENDER PYLE, M. Am. Soc. C. E.[1]

Died April 20, 1944

Milton Allender Pyle was born in Baltimore, Md., on August 24, 1894, the son of Benjamin Franklin Pyle and Laura (Allender) Pyle.

He attended the Baltimore public schools including the Baltimore Polytechnic Institute, from which he entered the University of Maryland at College Park. He was graduated in 1918 with the degree of Bachelor of Science in Civil Engineering. In 1937 the university conferred on him the professional degree of Civil Engineer.

Because of his excellent undergraduate academic record, Mr. Pyle was appointed instructor in civil engineering at his alma mater following graduation and began teaching in September, 1918. In October, 1932, he was promoted to assistant professor and in October, 1942, to associate professor of civil engineering.

Professor Pyle's chief teaching interest was in the fields of surveying, drawing, and descriptive geometry. He spent several of his summer vacations with the Washington Suburban Sanitary Commission on surveys and construction to develop sanitary facilities in the metropolitan area surrounding Washington, D. C. Other summers he spent surveying and mapping the property of the University of Maryland and in laying out a large subdivision in the vicinity of College Park. In the summer of 1937 he served as instructor in surveying at the Yale Engineering Camp at East Lyme, Conn.

During the summer of 1938 he was engineer of surveys for the firm of the late J. E. Greiner, Hon. M. Am. Soc. C. E., of Baltimore, which was consultant to the Maryland State Roads Commission. Professor Pyle had charge of several field parties on the preliminary surveys for the primary bridge program of Maryland. The projects consisted of the bridge at Havre de Grace across the Susquehanna River; the bridge at Ludlow's Ferry across the Potomac River; the proposed bridge across the Patapsco River in Baltimore; and the proposed bridge across the Chesapeake Bay at two tentative locations, one in the vicinity of Baltimore, from Miller's Island to Tolchester, and the other in the vicinity of Annapolis from Sandy Point to Kent Island. Most recently he served as engineer for the Advisory Board to the County Commissioners of Prince Georges County, Maryland.

---

[1] Memoir prepared by S. S. Steinberg, M. Am. Soc. C. E.

Professor Pyle was unusually successful as a teacher. He spent considerable time and effort revising and perfecting his courses to keep his students in touch with the newest developments in his special fields. He exemplified to a high degree the qualities of loyalty and devotion to duty, and his passing is a great loss to his colleagues on the faculty, as well as to the University of Maryland in whose service he spent more than a quarter of a century.

He was a member of Tau Beta Pi, the National Society of Professional Engineers, and of Sigma Phi Sigma social fraternity.

On June 5, 1919, Professor Pyle was married to Anna Elizabeth Hunter at Baltimore. He is survived by his widow and a daughter, Shirley Dell (Mrs. Paul T. Lanham).

Professor Pyle was elected a Member of the American Society of Civil Engineers on November 12, 1940.

ALFRED MERRITT QUICK, M. Am. Soc. C. E.[1]

DIED MARCH 31, 1944

Alfred Merritt Quick was born at Seymour, Conn., on February 10, 1867, the son of Abram J. and Frances (Merritt) Quick. He was graduated from Brown University in Providence, R. I., in 1887 with the degree of Bachelor of Philosophy. Immediately after graduation, he entered the city engineer's office in Providence, where he was engaged as a draftsman on a new sewerage system, designing buildings for the Public Works Department.

Early in Mr. Quick's career, he was undecided as to whether to practice as an engineer or an architect, but eventually he decided to become an engineer.

Until 1894, with the exception of six months as a draftsman in the office of the city engineer at Lockport, N. Y., Mr. Quick continued to work in the city engineer's office in Providence. Because of his interest in water works and sewer systems, Mr. Quick decided to further his knowledge in these fields and entered the employ of the late Samuel M. Gray,[2] M. Am. Soc. C. E., a consulting engineer of Providence. In this capacity, he designed and wrote reports on water works and sewer systems. From 1897 to 1898, he was assistant engineer in the Water Department of Baltimore, Md., in charge of $2,000,000 worth of new improvements. Through experience, he finally determined that the water systems were most appealing to him. Between 1898 and 1900 he engaged in private consulting practice in Baltimore with the late Nicholas S. Hill, Jr.,[3] and the late Kenneth Allen,[4] Members, Am. Soc. C. E., under the firm name of Hill, Quick and Allen. Although the firm specialized in designing and investigating water works, it was also engaged on sewer systems, street railways, general engineering, and work for electric light and gas companies.

---

[1] Memoir prepared by George E. Finck, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXV (1922), p. 1679.

In 1900 Mr. Quick was offered a position as chief engineer of the Baltimore Water Department and also was made president of the Baltimore Water Board. In addition, he was a member of the Board of Public Improvement of Baltimore. He served in these positions during three civic administrations. One of the first engineers to utilize chlorine in the treatment of water, Mr. Quick had studied the further treatment of water by use of sand beds although he seemed to favor the slow sand filter method of treatment. During this period, he was in charge of all construction of reservoirs, standpipes, and buildings and also was consulting engineer to a number of water companies, making investigations and reporting on improvements.

Between 1911 and 1922, because of a change in city adminstration, Mr. Quick entered private practice as consulting engineer on water works, sewer systems, hydroelectric plants, and mining, principally in Maryland, Virginia, West Virginia, and Pennsylvania.

About this time the United States Fidelity and Guaranty Company contemplated the establishment of an Engineering Department—an unusual action for a bonding company. In 1922 Mr. Quick was selected as chief engineer of this department. He served in this capacity until his death, acting as an adviser on contract bond underwriting and settling claims, as well as giving any necessary engineering advice.

Mr. Quick was modest in his dress and taste. He was liked by his associates, and all those who came in contact with him respected not only his engineering ability, but also his integrity. Although he gave up architecture as a vocation, it was evident that his ability as an excellent freehand sketcher would have been of material help in this particular profession.

Mr. Quick's personality is well summarized in the following statement by the Rev. A. Brown Caldwell, pastor of the Walbrook (Baltimore) Presbyterian Church, which Mr. Quick attended:

> "Alfred M. Quick was one of those unusual characters of whom it is difficult to form an estimate, except that he was an unusual man, that he did not conform to pattern or standard and that you could expect from him a refreshing attitude and a startling response.
>
> "He was a man of sharp, precise and unorthodox opinions. He was strong in both his attachments and his prejudices. Few men of my acquaintance have been more devoted to their family than was he, and equally few men as intolerant of the foibles and misrepresentations which creep into our lives. He would make any sacrifice, sometimes seeming to border on

[3] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 103 (1938), p. 1808.

[4] For memoir, *ibid*, Vol. 95 (1931), p. 1437.

the unreasonable, for his family, yet he would refuse even a crumb of charity if he believed the seeker to be unworthy or the cause in any way unjust.

"He was consistent in this attitude to Spartan extent. His wife recounted how he was once offered a princely sum of money to betray some information which would enable others to make gain but his stern sense of honor made him scornfully refuse to enrich himself because he regarded his public trust so highly. Yet he would lavishly minister to the whims of his children and friends with no selfish thought for himself at all.

"He seconded, throughout his family life, the deep religious devotion of Mrs. Quick. He gave of himself unstintingly to the service of the Walbrook Presbyterian Church to which he belonged. His service as Chairman of the Board of Trustees of that Church for many years resulted in improvements in its physical property and advantage in its spiritual outreach. He liked his minister and was markedly devoted to the program. But he would return to his home without entering the Church on a given Sunday if he found a stranger in the pulpit whom he did not know on occasions when his own minister might be called from the Church for some other service. His expressions of appreciation of a sermon presentation, or of some other service by the minister or a church officer, were of the same emphatic nature as was most everything else Mr. Quick did. They were most decided, almost superlative, if given at all. And he was just as ready to condemn aggressively and emphatically that with which he found cause to disagree. His attitude in politics, in social matters and in nearly all that he did was one of extremes.

"Mr. Quick was a voracious reader and in this field he carried his attitude of extremes to an unusual end. Conceiving the idea that American writers produced inferior works, he consistently refused to read the works of American authors, especially those currently issuing books, and read instead the works of other writers.

"Perhaps his attitude may have been born of an innate shyness and a deep humility of nature. But this very fact enabled him to develop his own mind so that he was capable of nearly instant judgment both of human character and in other matters. His well-trained engineering mind was able very quickly to form a judgment about a problem presented, or a case submitted. He preferred to take the matter in hand to his own mind, form his own opinion and deliver his judgment. He was not given to laboring the point with others, did not customarily indulge in debate, but was firm in his convictions when once established and held tenaciously to his judgments when given."

Mr. Quick never joined any fraternal organizations as he often expressed the opinion that his Society badge was all the professional entrée that was needed. He was efficient in his work and strong in his likes and dislikes. When preparing any papers or articles, he was very thorough and spent much time obtaining accurate information. His papers included articles on "The Cost of Modern Fireproof Buildings," "The Analysis of the Mississippi Flood Control Project and Cost," and "Water Service of the Baltimore Fire in February 1904." He wrote a comprehensive small history of the Baltimore Engineer's Club. He was a member of Sigma Xi fraternity and the Casualty and Survey Club of Baltimore, and an honorary engineer associate of the Engineer's Club of Baltimore.

Mr. Quick was elected an Associate Member of the American Society of Civil Engineers on October 5, 1898, and a Member on May 3, 1910.

AARON ISRAEL RAISMAN, M. Am. Soc. C. E.[1]

DIED JULY 11, 1943

Aaron Israel Raisman, a native New Yorker, was born on November 9, 1873, the son of Joseph and Minna (Rubin) Raisman. He received his education in New York City—first in the public schools and later at Columbia University, from which he was graduated with the degree of Civil Engineer in 1898.

His entire professional career extending over four decades (except for two years on the engineering staff of the Central Railroad Company of New Jersey after his graduation from Columbia) was devoted to the planning and design of rapid transit railroad structures for the City of New York. He was first employed as draftsman and assistant engineer under the late William Barclay Parsons,[2] Hon. M. Am. Soc. C. E., then chief engineer of the Rapid Transit Commission, on the first subway built in New York. Mr. Raisman's outstanding ability was soon recognized. He was promoted to positions of progressively increasing responsibility and closed his career as chief designing engineer in 1938—when the last construction contracts of the $670,000,000 Independent Division of the New York City Transit System, popularly known as the Eighth Avenue Subway, were nearing completion. He was one of the small pioneer group of engineers who developed the basic design features of New York City subways.

The engineering design of the Eighth Avenue Subway—consisting of a four-track trunk line, a distributing loop in the inner part of the city, and branches extending into four of the five boroughs of New York—was under Mr. Raisman's direction from the beginning of construction in 1924 until his retirement in 1938. This project comprises fifty-nine route miles of subways, land tunnels, and subaqueous river crossings, in addition to yards, shops, and auxiliary structures. This municipally planned and operated railroad includes two hundred miles of operating track and more than one hundred passenger stations of various types. As of 1944 it carried one-and-one-half-million passengers a day with an ultimate capacity of two million passengers a day. During the height of the work when construction proceeded at the rate of $250,000 per day (believed to be a prewar record for a single project) Mr. Raisman directed a designing force of seven hundred engineers and draftsmen.

His previous work—on the planning of subways, tunnels, and elevated railroads of the first rapid transit subway in the Borough of Manhattan and the Borough of the Bronx and extensions into the Borough of Brooklyn, the Center Street Loop in Manhattan, the Brooklyn-Fourth Avenue Subway, and the dual system subways—would in itself be considered a major achievement for an active lifetime. Many of the improvements in the basic plan and in the design, keeping pace with new and improved materials and changing methods of construction, originated with Mr. Raisman.

---

[1] Memoir prepared by Alfred Brahdy, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 98 (1933), p. 1485.

His services were not confined to rapid transit problems of the metropolis. His advice was often sought on other municipal engineering works, and he was also consulted on rapid transit projects of other cities both in the United States and abroad. To this work he applied a combination of enthusiasm, endurance, patience, and understanding that promoted teamwork and achieved results. His keen analytical mind was quick in sizing up the fundamentals of an engineering project, and he was able also to visualize the details as well as the collateral problems. He was generous to a fault in giving credit when suggestions were made by others, and, sometimes, when things did not turn out as had been expected, he assumed the responsibility on behalf of his subordinates. His primary consideration always was the good of the work rather than personal success.

Mr. Raisman's life was one continuous record of unselfish public service for the City of New York and of loyalty to his superiors and to those who worked with him or for him. His helpful understanding extended far beyond his professional duties and many a man is indebted to him for guidance and good advice. His retirement was keenly felt by all of his associates. After he retired as chief designing engineer for the Board of Transportation of the City of New York in April, 1938, he devoted his time to travel and to his family.

Mr. Raisman recorded some of his ideas and achievements in technical publications.[3,4,5] However, the enduring record of his achievements is incorporated in the steel and concrete of the municipal rapid transit structures of the City of New York and in the hearts of his associates.

On September 10, 1900, in New York City, Mr. Raisman was married to Emma Behrman. He is survived by his widow; two children, Lucy (Mrs. Leonard Passell) and Victor Raisman, M. D.; and two grandchildren, Margery Raisman and Nicholas Passell.

Mr. Raisman was elected a Member of the American Society of Civil Engineers on June 16, 1924.

FREDERICK HOSEA RICHARDSON, M. Am. Soc. C. E.[1]

DIED NOVEMBER 5, 1944

Frederick Hosea Richardson, the son of Samuel H. and Henrietta (Hutaff) Richardson, was born in Detroit, Mich., on December 10, 1882. He attended

[4] "Advances in Subway Design and Equipment," by A. I. Raisman, *ibid.*, January, 1933, p. 21.

[5] "Some Elements of Subway Design," by A. I. Raisman, *Municipal Engineers Journal*, First Quarterly of 1926, p. 15.

[1] Memoir prepared by Ralf R. Woolley and R. K. Brown, Members, Am. Soc. C. E.

the public schools of Seattle, Wash., and the civil and mechanical engineering schools of the University of Washington at Seattle. He was a member of the Sigma Nu fraternity.

Mr. Richardson served the Oregon Short Line Railroad Company, the Belcher Mountain Railway Company, and the Clear Lake Railway Company on location, construction, and maintenance for about two years. For the next three years he was chief engineer on reconnaissance, location, and construction for the San Francisco, Idaho and Montana Railway Company (250 miles) in Montana.

From 1909 to 1911 he was a member of the firm of Richardson and Williams, civil engineers of Caldwell, Idaho, specializing in highway, municipal, irrigation, and reclamation work. During this period he was also city engineer of Caldwell in charge of various improvements to the water supply and distribution system, sewers and sewage disposal, complete city resurvey, street paving, sidewalks, etc. At this time he was also water commissioner for the Third District of the State of Idaho.

From the middle of 1911 until 1913, he was a member of the firm of Richardson and Richardson, civil and mining engineers, at Republic, Wash., and was also deputy county engineer of Ferry County, Washington. For the next year and a half he was assistant engineer for the Washington State Highway Department in charge of location and construction of state highways in Ferry County.

From September, 1919, to December, 1920, Mr. Richardson served as examiner, senior examiner, senior negotiator, and assistant to the adjuster of the United States Shipping Board, Emergency Fleet Corporation, in charge of appraisals of all materials on hand in all shipyards in the Pacific Northwest.

Beginning in January, 1921, for the next fourteen months he was assistant engineer for the Washington State Highway Department on location and construction in Jefferson County. On March 2, 1923, Mr. Richardson became field engineer for the Portland Cement Association at Spokane, Wash. He served in this capacity for twenty-seven months and then for five years as district engineer. During the next ten and one-half years he was consulting engineer for the same association at Salt Lake City, Utah. He was employed by the Portland Cement Company of Utah until his death.

While working for the Portland Cement Association at Salt Lake City, he was chairman of the Salt Lake County Committee of the Civil Works Administration, member of the board of consulting engineers for projects of the Reconstruction Finance Corporation in Utah, member of the Utah State Board of Engineering Examiners, member of the Utah Water Storage Commission, and member of the Salt Lake County Relief Committee.

During World War I, from January, 1918, to August, 1919, Mr. Richardson was Captain, Corps of Engineers, U. S. Army, serving as Company Commander and later as Commanding Officer of the 526th Engineers. He was also Engineer Officer in charge of the construction of various projects for the Advanced Section, the Services of Supply, and the American Expeditionary Forces and was in France for one year.

While in Salt Lake City he became a Major in the Corps of Engineer Reserve, U. S. Army, serving under Gen. Walter C. Sweeney, Commanding Officer at Fort Douglas, Utah. Major Richardson made comprehensive studies and reports on the theory that, in case of war, Fort Douglas would become headquarters for the 9th Corps Area (later the Ninth Service Command) which it did in January, 1942. For that purpose he planned and had charge of extensive improvements at Fort Douglas.

On November 2, 1940, Major Richardson was ordered to active duty as a Lieutenant Colonel, Corps of Engineers, and was in turn Executive Officer at the Recruit Reception Center at Fort Douglas; Constructing Quartermaster, Area Engineer, at Fort Dix, N. J.; Assistant to District Engineer at Philadelphia, Pa., as Chief of Operations and Executive Officer; student, Engineer Supply School; Assistant to Engineer Supply Officer as Chief, Control Unit, at the Columbus (Ohio) Quartermaster Depot; and Engineer Supply Officer, Richmond, Va. (Quartermaster) Army Service Forces depot.

On September 30, 1943, Colonel Richardson was granted a leave of absence until December 30, 1943, at which time he reverted to inactive status. He rendered signal service to the United States—in fact, he so faithfully and fully devoted himself to his Army duties that his health was seriously impaired, and a month or so before his death he entered the Veterans Hospital for observation and treatment. However, this was to no avail as his heart finally failed and he died on November 5, 1944.

In November, 1943, he returned to Salt Lake City, of which he was very fond, with the expectation of making it his permanent residence.

On March 31, 1918, Colonel Richardson was married to Mary E. Lucas of Seattle, at Petersburg, Va. He is survived by his widow and two sons, William H. (Second Lieutenant, Corps of Engineers, U. S. Army) and Frederick L. (Second Lieutenant, U. S. Army Air Corps).

Colonel Richardson was a member of the American Concrete Institute, the Salt Lake City Rotary Club, Salt Lake City Chamber of Commerce (for which he served on many committees), and the Utah Society of Professional Engineers. He was licensed to practice engineering in Utah. He was also second vice-president of the Utah Chapter of the Society of American Military Engineers and was a Thirty-Second Degree Mason, a Noble of the Mystic Shrine, and a member of El Kalah Temple in Salt Lake City. Colonel Richardson belonged to the Advisory Board of the Utah Engineering Experiment Station. Previously he had served as a member of the Advisory Committee of the Civil Engineering Department of the University of Utah, at Salt Lake City. During the winter of 1943–1944 he was a part-time instructor in Civil Engineering at the university. For many years, until his death, he served ably as Secretary of the Utah Section (later the Intermountain Section) of the Society.

Much interested in good government, he was active in many phases of civic life and service and was particularly concerned about the welfare of the younger members of the engineering profession. He possessed a genial personality with a broad outlook on life and was highly respected for his fairness and constructive vision. His death was a distinct loss to the community.

Colonel Richardson was elected an Associate Member of the American Society of Civil Engineers on September 5, 1911, and a Member on July 8, 1941.

ALLAN TOWNSHEND RICKETTS, M. Am. Soc. C. E.[1]

Died October 31, 1944

Allan Townshend Ricketts, the son of Thomas Hugh Ricketts and Cora Hanson (Townshend) Ricketts, was born in Baltimore, Md., on June 23, 1883.

He proved an exception to the rule that men who are employed for several years immediately after graduation from high school seldom obtain a university education. Mr. Ricketts was graduated from high school in Summit, N. J., in 1903 and immediately started his career as a rodman, instrumentman, and assistant engineer on municipal and railroad construction and maintenance. He left the employ of the Cincinnati, Hamilton and Dayton Railway Company at Cincinnati, Ohio, in 1911, to enter the University of Michigan at Ann Arbor.

Allan Ricketts was graduated from the University of Michigan in 1915 with the degree of Bachelor of Science in Civil Engineering. His major subject was sanitary engineering. From 1915 to 1927 he was engaged by N. S. Hill, Jr.,[2] M. Am. Soc. C. E., as assistant engineer and later as associate engineer on design and construction of water and sewer systems of considerable magnitude, including treatment plants for both water and sewage. In 1927 he was appointed deputy chief engineer of the Public Works Engineering Corporation and later of its successor, the Trojan Engineering Corporation. Both these companies were engineers for the Federal Water Service Corporation. During this engagement he conducted investigations for new water supplies throughout the United States. He also supervised design and construction of many important municipal water supplies and distribution systems.

Mr. Ricketts entered government service in Washington, D. C., in 1932 and remained in federal employ until failing health compelled his retirement in 1943. He first joined the staff of the Reconstruction Finance Corporation. In July, 1933, he transferred to the Public Works Administration (PWA). In PWA he served, successively, as engineer examiner, assistant chief engineer, and chief engineer. After the Federal Works Agency (FWA) was established, he became consultant in the office of the chief engineer of that agency, remaining until his death.

Many million dollars worth of federally financed sanitary engineering construction felt Mr. Ricketts' sound and conservative influence when he was with PWA and FWA. His broad engineering experience, knowledge, and ability were recognized as of outstanding value in water works, sewerage, and municipal engineering. His booklet on "Diagram for the Solution of Problems by Williams and Hazen Formula for Discharge of Pipes," first distributed in 1934, has provided a most useful method for direct solution of hydraulic problems in water works engineering.

---

[1] Memoir prepared by a Committee consisting of H. H. Jewell and W. N. Carey, Members, Am. Soc. C. E.; H. S. Devlin, Assoc. M. Am. Soc. C. E.; and G. L. Rounds, Engr., Federal Works Agency, Washington, D. C.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 103 (1938), p. 1808.

In addition to his membership in the Society, which he prized, Mr. Ricketts belonged to the American Society for Testing Materials, American Public Health Association, Federal Sewage Research Association, Washington Golf and Country Club, and Capital City Chess Club. His devotion was first to his family and then to his profession. His principal hobby was golf at which he was expert. He made and retained a host of friends who will miss him. The engineering profession has lost an able leader.

He is survived by his widow; a son, Allan T. Ricketts, Jr.; and a daughter, Jane (Mrs. James G. Thomas).

Mr. Ricketts was elected a Member of the American Society of Civil Engineers on September 9, 1919.

FRANKLIN HENRY ROBBINS, M. Am. Soc. C. E.[1]

DIED MARCH 12, 1944

Franklin Henry Robbins was born in Yonkers, N. Y., on August 31, 1872, the son of Charles T. and Mary L. (Dewers) Robbins.

During his boyhood the family moved to Corsicana, Tex.; then to Toledo, Ohio, and finally to Kingston, Mass., where Mr. Robbins was graduated from the Kingston High School in 1890. Mr. Robbins attended the Massachusetts Institute of Technology, then in Boston, being graduated in 1894 with the degree of Bachelor of Science in Mechanical Engineering.

Before graduation, during his summer vacation in 1893, he acquired practical engineering experience as transitman on street railway construction for Hodges and Harrington of Boston. Soon after graduation he worked for five months as draftsman for the Peckham Motor Trunk and Wheel Company of Kingston, N. Y. From December, 1894, to February, 1897, he was assistant in mechanical drawing and descriptive geometry at the Massachusetts Institute of Technology. During the first of his summer vacations he served as draftsman and instrumentman on maps, surveys, and estimates for the city engineer of Cambridge, Mass., and during the second as machinist for the E. H. Howard Watch and Clock Company of Boston.

From February, 1897, to March, 1903, Mr. Robbins was transitman with the Boston Water Works and designer for the Metropolitan Water Board of Massachusetts on surveys, experimental work, inspections, designs, and estimates. From March, 1903, to December, 1903, he was draftsman and computer on designs and estimates for the Commission on Additional Water Supply of New York, N. Y. He then worked three years and four months for the Bureau of Filtration of Pittsburgh, Pa.—for eleven months as assistant engineer on design, and in charge, under the principal division engineer, of the preparation of contract drawings and specifications for a pumping station; and then for two years and five months until September, 1907, as division engineer in charge of construction of the pumping station, river intake, river protection, and the examination of submitted drawings of machinery and boilers.

---

[1] Memoir prepared by Halsey French and Wilbur T. Wilson, Assoc. Members, Am. Soc. C. E.

From Pittsburgh, Mr. Robbins went to New York and in August, 1907, began thirty-five years of service in the Headquarters Department of the Board of Water Supply of the City of New York. For twenty years he was assistant designing engineer, and for the remaining fifteen years until his retirement on August 31, 1942, he was a designing engineer. During this period his work on the Catskill Aqueduct and the Delaware Aqueduct projects of the Board included designs, basic hydraulic determinations, experimental work, specifications and investigations for cut-and-cover aqueducts, grade tunnels, shafts, pressure tunnels, dams, bridges, steel and cast-iron pipe lines, sewage disposal plants, sanitary works, aerators, coagulating plants, chlorinating installations, and flow control chambers, together with all incidental and appurtenant designs.

He was a life member of the Boston Society of Civil Engineers and the New England Water Works Association; a member of the Municipal Engineers of the City of New York; and, for some thirteen years, an active member of the American Water Works Association.

On September 5, 1899, he was married to Marie Joubert-LaLoge in Boston. He is survived by his widow; two sons, Charles LaLoge Robbins and Henry Fuller Robbins; a granddaughter, Jean, daughter of Charles L. Robbins; a brother, Leavitt T. Robbins; and two sisters, Emily C. Robbins and Helen D. Robbins.

From boyhood, Mr. Robbins was very fond of music and excelled as a cornet player. He frequently attended the opera and concerts of symphony orchestras. While a resident of Cambridge, he was a member of the Bohemian Orchestral Club, an amateur musical organization composed largely of Harvard University men.

For many years he spent his vacations in New Hampshire fishing or occupying himself with craftwork in copper or britannia metal. He was very skilful in this craftwork and made many objects—both useful and ornamental.

He was gifted as an engineer and possessed a keen perception, an analytical mind, a most retentive memory, and was painstaking, thorough, and indefatigably industrious. Mr. Robbins left behind him a record of marked excellence and accomplishment on major engineering work. An innate modesty and reserve never concealed, however, his outstandingly high qualities of heart and mind which won for him the highest respect and esteem of those who knew him.

Mr. Robbins was elected an Associate Member of the American Society of Civil Engineers on July 10, 1907, and a Member on October 7, 1929. He became a Life Member on January 1, 1942.

JOHN McCLURE SALMON, M. Am. Soc. C. E.[1]

DIED JANUARY 30, 1945

John McClure Salmon, the son of Anderson and Edna (McClure) Salmon, was born in Washburn, Mo., on June 3, 1878. He received his education in public schools and at the University of Missouri in Columbia, from which he was graduated in 1902 with honors in Civil Engineering.

From May, 1902, to June, 1902, Mr. Salmon was employed by the St. Louis, Memphis and Southeastern Railway. He was with the consulting engineering firm of Brenneke and Fay from June, 1902, to June, 1903, and with the Terminal Railroad Association of St. Louis (Mo.) from June, 1903, to June, 1906.

He began to work for the Louisville and Nashville Railroad Company in June, 1906. He remained with this company until April, 1914. During this period he was engaged in design work, as well as in field supervision of wrecks and storms.

In April, 1914, Mr. Salmon left the Louisville and Nashville Railroad Company to become chief engineer and general manager of the Louisville Bridge and Iron Company, continuing until September, 1917, at which time he returned to the Louisville and Nashville Railroad Company as bridge engineer. He served in this capacity until his death.

Some of the most important structures which Mr. Salmon designed and constructed for the Louisville and Nashville Railroad Company are the Rigolets and Chef Menteur bridges in Louisiana; the Tensas River Bridge near Mobile, Ala.; the Ohio River bridge at Henderson, Ky.; and the Tennessee River Bridge at Danville, Tenn.

Mr. Salmon had many friends. He was a fine, honest, upstanding man, and all those who knew and worked with him loved him. Honesty, loyalty, the spirit of self sacrifice, belief in fair play, and tolerance were his outstanding characteristics. His willingness to help a friend or associate and his kindliness toward others were among his finest traits. He took great pride in his profession and work. He was a member of Tau Beta Pi, an honorary engineering fraternity, and the American Railway Engineering Association. He was active on many committees.

On November 27, 1902, Mr. Salmon was married to Elizabeth Jane Wood, at Independence, Mo. He is survived by his widow; two sons, J. M. Salmon, Jr., and Gordon W. Salmon; one granddaughter, Barbara; and three grandsons, Gordon, Jr., J. McClure II, and Robert M.

Mr. Salmon was elected a Member of the American Society of Civil Engineers on June 4, 1913.

---

[1] Memoir prepared by H. G. Livesay, Assoc. M. Am. Soc. C. E.

GEORGE ARTHUR SEAVER, M. Am. Soc. C. E.[1]

Died January 20, 1945

George Arthur Seaver was born in New Orleans, La., on November 23, 1886. He was the son of Marjorie (Ford) Seaver of Virginia and George Arthur Seaver of New York State.

He attended Ferrill's School and upon graduation went to Tulane University in New Orleans where he entered the School of Civil Engineering. Desiring to earn his own way through college he worked during his vacations, and remained out of college for about two years, gaining valuable experience.

In 1903 he worked in the Johnson Ship Yards in Algiers, New Orleans. From June, 1904, to October, 1905, he was with Sanderson and Porter, engineers of New York, N. Y., as rodman, draftsman, and instrumentman on underground utilities and cables for the New Orleans Public Service. He also worked on the construction of the Market Street powerhouse and Elysian Fields Avenue substation and tunnel. From June, 1907, to October, 1908, he was assistant general superintendent of construction for A. B. Stannard on the building of the New Orleans Court House. In 1910 he was graduated from Tulane University with the degree of Bachelor of Engineering in Civil Engineering.

After graduation, Arthur Seaver entered the employ of George J. Glover, a general contractor specializing in building construction. In 1924 when the organization was incorporated as George J. Glover Company, Inc., he was taken into the firm. Mr. Seaver became well known for handling subcontracts and directing construction. He was project manager on the construction of the LaGarde General Hospital for the U. S. Army, which was the first of the rush projects to be built in New Orleans, and then took over the direction of the construction of the Consolidated Vultee Aircraft Plant, a $7,000,000 project built by his company for the Defense Plant Corporation.

In 1916, during the Mexican border trouble, Arthur Seaver enlisted in Battery C of the Washington Artillery and served with this unit on the Mexican border as a chief mechanic.

Arthur Seaver delighted in doing work with tools, repairing and constructing around his home. Tennis was his lifelong hobby, and he participated actively in this sport throughout his lifetime. He was a member and past-president of the New Orleans Lawn Tennis Club, one of the oldest tennis clubs in the United States; and, while engaged in a match of doubles, he was fatally stricken on January 20, 1945. He studied the design and construction of tennis courts, and developed a design for a brick dust court which was extremely popular and successfully used at the New Orleans Lawn Tennis Club and in the parks of New Orleans. He was always experimenting with new ideas for the improvement of this type of court.

---

[1] Memoir prepared by a Committee of the Louisiana Section consisting of Bernard H. Grehan, Chairman, and John Riess, Members, Am. Soc. C. E., and Charles M. Kerr, Assoc. M. Am. Soc. C. E.

In the professional field, by virtue of his large circle of acquaintances and his experience and ability, Mr. Seaver became an outstanding figure in the building construction field. His death was a great loss, not only to his associates, but to the entire building industry in Louisiana. He was a life member of the Louisiana Engineering Society.

In 1921 he was married to Nellie Fischer. Mr. Seaver is survived by his widow and by three children, Elizabeth (Mrs. Gelon Hann Doswell), George Arthur Seaver, III, and John Wyman Seaver.

Mr. Seaver was elected a Member of the American Society of Civil Engineers on May 18, 1943.

CHARLES FRANK SEIFRIED, M. Am. Soc. C. E.[1]

DIED JULY 21, 1943

Charles Frank Seifried, the son of Frank and Josephine (McGowan) Seifried, was born at Chicago, Ill., on October 3, 1885. While he was still quite young, his parents moved to Denver, Colo., where he completed the regular public grade and high school courses. He studied general engineering subjects at Stanford University, Stanford University, Calif., from September, 1903, to January, 1905. In September, 1906, he entered Cornell University at Ithaca, N. Y., from which he was graduated with the degree of Civil Engineer in June, 1909. From January, 1905, to September, 1906, and during the summers of 1907 and 1908 while attending Cornell University, he worked for the Union Pacific Railroad Company in Colorado—first as rodman, later as instrumentman, and finally as foreman on miscellaneous railroad construction and maintenance jobs, including some highway and power-line construction.

Like many young engineers, his first few years after leaving school were spent in various places on different assignments. From September, 1909, to December, 1917, Mr. Seifried held the following positions:

September, 1909, to December, 1910—with the St. Louis, Iron Mountain and Southern Railway Company at Van Buren, Ark., first as assistant in the engineer's corps, and later as assistant engineer on general maintenance work.

December, 1910, to February, 1911—with contractors on highway improvement work in Colorado, in charge of concrete bridge and culvert construction.

May, 1911, to May, 1912—with Reitze, Story and Duffy, at Seattle, Wash., for six months as instrumentman and inspector on street improvement work and for six months as chief of survey party on railroad location.

May, 1912, to May, 1913—with the Clear Lake (Washington) Lumber Company, on location of logging roads, construction of trestle bridges, and topographic mapping.

June, 1913, to December, 1914—with Boynton and Church and Guthrie-

---

[1] Memoir prepared by W. H. Fisher, Assoc. M. Am. Soc. C. E.

McDougal, contractors, in the State of Washington on heavy railroad construction, including five months in charge of a grading camp of fifty men and considerable time in charge of concrete and other construction.

May, 1915, to December, 1917—with the U. S. Interstate Commerce Commission, Division of Valuation, as junior railway civil engineer, in charge of cross-section work and track parties on inventory for various western railroads.

In May, 1917, he applied for a commission in the U. S. Army Engineer Corps for service in World War I. He was assigned to Officers' Training Camp at Petersburg, Va., in January, 1918, where he was made a Second Lieutenant. Assigned to the Twenty-Third Engineers at Camp Laurel, Maryland, he later sailed for France on March 28, 1918, and saw fourteen months of active service there in charge of highway and railroad construction and maintenance, during which time he became a First Lieutenant. He was honorably discharged from the Army in July, 1919.

In August, 1919, immediately after his discharge from the Army, Mr. Seifried was employed by the Wyoming State Highway Department, as resident field engineer on highway construction. Within one month, however, he was called into the headquarters office of the department at Cheyenne, Wyo., as chief draftsman and head designing engineer. He here had full charge of preparing the detail plans for all future highway projects, for eighteen years, or until September, 1937. During this period he was directly responsible for the complete plans and specifications used on the construction of some 3,300 miles of primary and secondary state highways.

In September, 1937, the State Highway Commission, having long since recognized his ability, appointed Mr. Seifried state highway superintendent, the highest office in the department. In March, 1939, because of a change in the state administration, he temporarily relinquished this position to become chief engineer of the department. In this latter capacity, he acted as principal assistant and consultant to the superintendent, but still retained full charge of all field and office engineering personnel and work, supervised the expenditure of all departmental funds, and handled a major part of the main office correspondence.

During May, 1942, while on a routine inspection trip in the northeastern part of Wyoming he was suddenly stricken by a severe heart attack. Brought to Cheyenne by ambulance, Mr. Seifried remained hospitalized until the following December before being able to resume work. In January, 1943, the State Highway Commission reinstated him as superintendent with the title of state highway superintendent and chief engineer. He retained this position until his death.

On July 21, 1943, while on an inspection trip with the state highway commissioners, at Cody, Wyo., he was suddenly stricken by a second heart attack, which at once proved fatal. His sudden death came as a great shock, not only to the entire personnel of the State Highway Department, among whom he was always familiarly known as "Si," but likewise to his many hosts of friends both in Cheyenne and over the entire state.

Despite his arduous duties in the State Highway Department, Mr. Seifried had always managed to find time through the years to engage in many worthwhile outside activities, in which he filled many positions of honor and responsibility. During the last three years of his life, he had served as "charge lay leader" in the Cheyenne Methodist Church, a position next in importance to that of pastor. He was vitally active in Blue Lodge and Scottish Rite Masonry, and had been Master of Blue Lodge, Acacia No. 11, at Cheyenne. He was actively interested in Boy Scout work, having served for several years as Cub Scout Leader. Always interested in professional affairs, he was president of the Western Association of State Highway Officials from June, 1941, to June, 1942; vice-president for Fourth District of the American Association of State Highway Officials from October, 1941, to December, 1942; president of the Cheyenne Engineers Club for 1925; president of the Wyoming State Board of Examining Engineers from February, 1935, until his death; president of the Wyoming Section of the Society for 1940; and vice-president of the Wyoming Engineering Society from January, 1943, until his death.

While in Seattle in 1911, Mr. Seifried first met his future bride, Lilian McGrew. They were married at Tacoma, Wash., in September, 1917. Two children graced their happy marriage—a son, Robert Dayton Seifried (in the U. S. Navy), and a daughter, Josephine Louise Seifried. By her whole-hearted devotion and high Christian ideals maintained through the years, Mrs. Seifried contributed much not only to the life and achievements of Mr. Seifried, but also to the welfare of the entire community. Mr. and Mrs. Seifried were at all times keenly active in the Cheyenne Methodist Church to which they belonged, and both always participated in any religious, educational, or civic betterment movement—either local, state, or national.

Any appraisal of Mr. Seifried's personality must of necessity list the following characteristics as being outstanding: His constant faith in his fellow men and his extreme optimism; his dynamic personality and the seemingly boundless energy and enthusiasm with which he would undertake a new job or grapple with an old one; his quickness to accept new situations as they arose and to act accordingly; his open frankness in all dealings; and his amazing capacity for work, matched only by his zeal for accomplishment. With such qualities it is only logical that it was with some difficulty that he could tolerate anything lackadaisical, either in word or in action. He was not a stickler for extreme nicety of form or for finespun theory beyond the lines of its practical application to some definite problem. These traits of character, too, were nicely balanced on occasion by his possession of a very keen sense of humor.

Remarkably noteworthy was Mr. Seifried's ability to remember details of any kind—whether these details were of some recent or of some long-past activity or conversation, or whether of some printed text or plan. Thus, his many inspection trips over Wyoming had made him thoroughly familiar with its every topographic detail, and during these trips he could commonly and offhand not only recall all essential construction details for any given highway section, but could also cite the date when built and the name of the constructing contractor. This happy faculty of recalling minute details, seemingly without effort, was naturally of great help to him throughout the years, particularly when state highway superintendent.

To summarize, Charles Frank Seifried was a man beloved by all who knew him. His sterling character and radiant good humor, his boundless optimism and enthusiasm in any undertaking, his stalwart Christian faith as exemplified in his daily life, and his tireless faithfulness to duty—these were qualities which drew to him the respect and admiration not only of his immediate associates in the State Highway Department, but of all others who knew him. In conclusion, as Edwin Markham has so aptly written of Abraham Lincoln, it may be truly said of Mr. Seifried:

> "He held his place—
> Held the long purpose like a growing tree—
> Held on through blame and faltered not at praise.
> And when he fell in whirlwind, he went down
> As when a lordly cedar, green with boughs,
> Goes down with a great shout upon the hills,
> And leaves a lonesome place against the sky."

Mr. Seifried was elected a Member of the American Society of Civil Engineers on January 9, 1939.

GILMAN WALTER SMITH, M. Am. Soc. C. E.[1]

DIED JULY 12, 1944

Gilman Walter Smith was born on December 1, 1859, in Red Wing, Minn., the son of Otis Smith and Margaret (Densmore) Smith. His forebears were all of good American stock. He was graduated from the University of Minnesota at Minneapolis in 1880, receiving the degree of Bachelor of Science.

Mr. Smith was first employed by the Chicago, Milwaukee, St. Paul and Pacific Railroad Company as a member of a field surveying party reporting to the division engineer's office in Minneapolis. In this capacity he was engaged on the location of a railway line from Norwood to Mankato, Minn. From 1881 to 1886 he worked for the same company in various positions beginning as rodman and advancing to assistant engineer, chiefly on maintenance of way. In 1886 he was transferred to the bridge and building department where he acted as chief carpenter, largely on inspection and construction of timber bridges for the South Minnesota Division. In 1888 he was promoted to assistant engineer on the inspection of bridges reporting to general headquarters at Milwaukee, Wis.

In 1890 the general offices were removed to Chicago, Ill., and he was transferred as assistant engineer to the staff of Onward Bates,[2] Past-President and Hon. M. Am. Soc. C. E., engineer and superintendent of bridges and buildings. In 1895 Mr. Smith became assistant superintendent of bridges and buildings, remaining with the railway company in this capacity until he resigned in 1901 to become erecting manager for the Western Division of the American Bridge Company of New York, N. Y., with headquarters in Chicago.

---

[1] Memoir prepared by Herbert S. Crocker, Past-President and Hon. M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 102 (1937), p. 1484.

There is no detailed record of his railway experience, but it is evident that Mr. Smith performed his duties most efficiently, or he would not have been consistently promoted to added responsibilities. He was painstaking and thorough in all the duties assigned to him.

After 1901 Mr. Smith enjoyed greater opportunities for responsibility and administration of the important work for which he had trained himself. As erecting manager for the Western Division of the American Bridge Company, he supervised the building of many large structures and bridges, including two railroad bridges across the Mississippi River—one at Thebes, Ill., and one at St. Louis, Mo.—and two bridges across the Missouri River—one at Omaha, Nebr., and the other at St. Joseph, Mo. His duties included the direction of arrangements, selection of methods and equipment, and responsibility for the safety, economy, and accounting of operations. The erection of bridges is not a simple procedure since varying sites and conditions demand methods entirely beyond routine and involve more careful planning, imagination, and courage than are generally realized either by the public or by the profession at large.

After leaving the bridge company in 1915, for two or three years Mr. Smith was engaged in personal affairs apart from engineering. From October, 1917, to March, 1918, he was employed by Metcalf and Eddy, consulting engineers of Boston, Mass., as resident engineer on the construction of a reinforced concrete reservoir for the city water supply of Dayton, Ohio.

Anxious to serve the United States in World War I, on March 15, 1918, Mr. Smith became a civilian employee of the Construction Division of the Army as personnel assistant to the executive officer of the building division. This work included interviewing, corresponding with, and judging the fitness of, applicants for commissions. He also supervised the records giving information regarding vacant positions and assignment of officers to duty.

On October 21, 1918, Mr. Smith was commissioned a Major, Quartermaster Corps, U. S. Army, and was assigned to duty with the administrative division. Later he was liaison officer to the commissioned personnel branch of the General Staff. He was honorably discharged on October 30, 1920. From November 1, 1920, to June 30, 1921, he was employed in the Real Estate Service of the War Department and in the Purchase, Storage, and Traffic Division of the General Staff.

From August 28, 1922, to August 31, 1924, Major Smith was senior structural engineer, with the Bureau of Valuation of the Interstate Commerce Commission. From October, 1924, until June 30, 1934, when he was retired by the U. S. Civil Service, he served as chief contract and record secretary, Construction Service, U. S. Veterans Administration.

After his retirement, he made a number of tours, including one to England, and finally settled in Los Angeles, Calif., where he supervised certain family estates and lived in comfort and good health.

A few months before his death, Major Smith entered the James Wadsworth Veterans Hospital near Santa Monica, Calif., as the result of an accident. He was buried in Arlington Cemetery in Washington, D. C.

The writer, who has known Major Smith since 1888, can truly state that Gilman W. Smith was an able engineer and an excellent administrator—logical and thorough in all his methods, fond of analysis, honest and loyal to those with whom he served. He had many admirable traits of character, being unselfish, always thoughtful of others, and active in the promotion of the welfare of his friends. Major Smith was a man of good habits, unpretentious but outstanding in his profession. There should be more engineers like him.

He was married in Minneapolis, Minn., in 1883 to Addie Anna Tidd. He was a member of the Universalist Church and, with Mrs. Smith, was always interested in church matters. After nearly fifty years of happily married life Mrs. Smith died in May, 1932, in Washington, D. C. Major Smith is survived by one son, Donald T. Smith.

From September, 1901, to December 31, 1919, Major Smith was a member of the Western Society of Engineers.

Major Smith was elected a Member of the American Society of Civil Engineers on March 2, 1909.

HOWARD EVERETT SMITH, M. Am. Soc. C. E.[1]

DIED JUNE 27, 1944

Howard Everett Smith, the son of Henry and Mary (Gay) Smith, was born at Waltham, Mass., on February 19, 1870.

His interest in engineering began with his employment by a firm of sanitary engineers in Natick, Mass., in 1888. This led to his attending the Worcester Polytechnic Institute at Worcester, Mass., from 1892 to 1894, when he shifted over to the Massachusetts Institute of Technology at Boston for the junior and senior years, graduating in 1896, with the degree of Bachelor of Science in Sanitary Engineering.

The next two years were spent on surveys for the Boston (Mass.) subway system then under construction. After the subway was opened, he became assistant to the civil engineer in charge at the Portsmouth (N. H.) navy yard, on the layout of buildings, installation of water and sewerage systems, and construction of a dry dock. From 1900 to 1906 he was an assistant civil engineer for the War Department in Ohio, constructing a breakwater at Fairport Harbor and having charge of a residency which included Ashtabula and Conneaut harbors.

In 1906 he went to New York State as an assistant engineer in the Department of the State Engineer and Surveyor, on the Barge Canal and the state highways, later with departmental rank of resident engineer. In 1909 when the highways were transferred from the control of the state engineer to a separate commission, Mr. Smith, with many other engineers, went over to the new department. He functioned as a resident engineer in the Syracuse Division and later as division engineer at Binghamton. In 1923 he transferred to the Rochester division. Not long afterward, in consequence of the merger of the several New York State construction bureaus into the State Department of Public Works, Mr. Smith became district engineer charged with design and construction of state and county highways in Monroe, Ontario, Livingston, Wyoming, Genesee, and Orleans counties, with general supervision of town and county road work, operation and maintenance of the Barge Canal from Lyons to Lockport, N. Y., and miscellaneous engineering projects inherited from the former state engineer's department. He retired in 1940.

---

[1] Memoir prepared by Percy Waller, M. Am. Soc. C. E.

Mr. Smith was of a rather reserved, retiring disposition, but behind this there was a great kindliness and richness of friendship. He was a man of high principles, of sound judgment, and of great executive ability—an excellent judge and manager of men. He was endowed with an exceptionally keen mind which evidenced itself in the clarity of his ideas and of his speech.

A prominent engineer, a friend of Mr. Smith for half a lifetime, writes: "Howard Smith was one of the finest men I ever knew insofar as his personal habits and traits were concerned and the attention which he devoted to his invalid wife and his family."

In 1901 Mr. Smith married Elizabeth Goddard. A son, Thorold Smith, and a daughter, Louise (Mrs. A. H. Knight), survive. Mrs. Smith died in 1938. It is almost a legend among the many who knew him how, when his wife became unable to walk, Howard Smith would carry her in his arms into church, concert, theater, or other places. In 1943 Mr. Smith married, this time Mabel C. Keehn of Rochester, who survives him.

He was a member of the national and New York State societies of professional engineers, a Thirty-Second Degree Mason, and a Rotarian.

Mr. Smith was elected a Member of the American Society of Civil Engineers on November 6, 1907.

GEORGE FRANCIS SPARHAWK, M. Am. Soc. C. E.[1]

Died May 3, 1944

George Francis Sparhawk was born in Randolph, Vt., on September 15, 1863, the eldest son of Luther Tucker and Josephine (Bean) Sparhawk. His grandfather and great-grandfather were Congregational ministers in Vermont.

His preparatory education was obtained in Randolph, and he was a member of the first class to be graduated from the high school. He entered Dartmouth College, at Hanover, N. H., in September, 1885, and was graduated in 1889 with the degree of Bachelor of Literature. He continued his engineering education in the Thayer School of Civil Engineering from which he was graduated in 1891 with the degree of Civil Engineer.

---

[1] Memoir prepared by C. F. Goodrich, M. Am. Soc. C. E.

After graduation, Mr. Sparhawk began at once to practice structural engineering—in which field he continued to specialize throughout his professional career. His first position was as assistant engineer with the R. F. Hawkins Iron Works in Springfield, Mass. He served in a similar capacity for George S. Morison,[2] Past-President, Am. Soc. C. E., consulting engineer; the Berlin Iron Bridge Company; and the Boston and Albany Railroad Company. In 1896 he became assistant engineer for the Union Bridge Company at Athens, Pa.

When the Union Bridge Company was incorporated in the American Bridge Company in 1901, Mr. Sparhawk became assistant engineer for the new firm. In 1903 he was transferred to the Ambridge (Pa.) Plant of the American Bridge Company, where he was promoted, successively, to squad foreman in the drawing room, to drawing room engineer, and, just before his retirement, to assistant to the plant engineer, as general consultant on special problems in the various drawing rooms. He retired in 1931 at the age of sixty eight from the American Bridge Company and from active engineering. All but five of the forty years of his professional career had been devoted to the American Bridge Company.

After his retirement from his chosen profession, Mr. Sparhawk sold insurance until he was forced to retire from all business activities because of failing health.

Those who knew George Sparhawk, who worked with him, or who were his neighbors in Beaver, Pa., will long remember his hearty manner, his ready smile, and his keen interest—not only in his work but in the humanistic side of life. He seldom wanted to talk about himself but always evinced much interest in other people. Always ardently enthusiastic about the Thayer School and Dartmouth College, he was able to attend the fortieth and fiftieth reunions of his class. He was a strong supporter of the American Society of Civil Engineers, attending the meetings of the Pittsburgh Section regularly and the Annual Meetings in New York, N. Y., whenever possible.

Mr. Sparhawk was an enthusiastic horseback rider and during the greater part of his active life kept one or two very fine saddle horses—some with such spirit that few besides himself dared ride them.

Mr. Sparhawk was married in 1896 to Jessie Burt of Orange, N. J. In addition to his widow, he is survived by two sons, John Burt and George Francis, Jr., and two grandchildren.

Mr. Sparhawk was elected a Member of the American Society of Civil Engineers on October 10, 1916.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LIV (June, 1905), p. 513.

ALLEN WHITMORE STEPHENS, M. Am. Soc. C. E.[1]

DIED MARCH 31, 1944

Allen Whitmore Stephens was born in Patten, Penobscot County, Me., on July 19, 1879, the son of Charles Walter and Susan Adella (Chadbourne) Stephens.

Mr. Stephens was graduated from the University of Maine, at Orono, in 1899, with the degree of Bachelor of Civil Engineering. In 1923 his alma mater recognized his outstanding engineering ability by conferring on him the honorary degree of Master of Science. He was a member of the Phi Kappa Sigma, Phi Kappa Phi, and Tau Delta Pi fraternities.

In June, 1899, he entered the engineering field as a draftsman for the New England Structural Company, at Everett, Mass. In March, 1901, he was employed by the American Bridge Company, as a checker and squad boss. In December, 1903, Mr. Stephens moved to Phoenixville, Pa., as a squad boss for the Phoenix Iron Company.

These positions were all in the field of structural steel design. The reinforced concrete industry, then in its infancy, attracted Mr. Stephens' attention. In September, 1905, he entered the employ of the Turner Construction Company, pioneers in concrete construction, first as a draftsman, then as a checker, chief draftsman, designing engineer, and finally as engineer. In May, 1919, he became chief engineer, and, from December, 1925, to September, 1926, he acted as general manager of the Chicago (Ill.) branch office. During these twenty-one years, all men who came under his direction learned to appreciate his kindly ways and honest dealings.

Mr. Stephens became vice-president of the Dresser Company of Cleveland, Ohio, in September, 1926, and continued in the field of general contracting until November 28, 1928, when he became a consulting engineer specializing in structural steel and concrete work and in expert court testimony. From November, 1933, to June 30, 1934, he was acting professor of civil engineering at the University of Delaware, at Newark, teaching highway, municipal, and structural engineering. He also served from May 1, 1935, until his death as a member of the Advisory Committee on Engineering, Public Buildings Administration, Federal Works Agency, Washington, D. C. As a consultant, he specialized in prefabricated demountable house design from October, 1940, to March 1, 1942.

Although an extremely busy man, Mr. Stephens found time to be chairman of the Building Code Committee of the American Concrete Institute, director in the New York City (N. Y.) Sunday School Association, trustee of the Moravian College and Seminary, in Bethlehem, Pa., and director of a boys' club. He was a member of the First Moravian Church of New York City and president of the Board of Trustees for many years. He served as chairman of the Board of Trustees of the Larger Life Foundation of the Moravian Church in America for twenty-four years.

---

[1] Memoir prepared by Alfred B. Heiser, M. Am. Soc. C. E.

Mr. Stephens belonged to the Engineers Club of New York, the Structural Engineers' Society of New York, the American Concrete Institute, the Western Society of Engineers, and the Newcomen Society.

He received the Maine Plaque with "M" for his services to the University of Maine through the alumni association, of which he was president for ten years.

On December 27, 1905, in Bethlehem, he was married to Marion Levering, who survives him.

Mr. Stephens was elected an Associate Member of the American Society of Civil Engineers on June 6, 1911, and a Member on May 8, 1922.

CHARLES HENRY STEVENS, M. Am. Soc. C. E.[1]

Died February 3, 1944

Attributes of character are formed during youth, and men are what their early experiences have made them. It is not accidental that many men who have risen to prominence in their chosen fields did so from a background of very limited opportunity, for responsibility in early life develops character. This is well illustrated in the career of Charles H. Stevens, whose father died when the boy was about eight years of age, leaving the widow and four children almost penniless.

Charles Henry Stevens was born in Harrisburg, Pa., on October 21, 1875, the son of William Franklin and Katherine (Marion) Stevens. Shortly after his father's death, Charles noticed one day that his mother appeared troubled. Upon inquiring, he learned that the mother's concern was due to lack of the necessary household money. The boy advised his mother not to worry, since he had sufficient money in his child's bank to take care of everything, and he thereupon turned over its contents for that purpose. The bank contained just two dollars! Here was a spirit unusual in a child, but one which was to be evidenced soon again.

Charles attended the public schools of Harrisburg, but left school, apparently at the age of eleven, and came to Philadelphia, Pa., with his mother in October, 1887. At the age of twelve, Charles entered into a nine-year apprenticeship agreement with a Philadelphia mechanical engineer, in order to provide for his own needs and for his mother's as far as he was able. The agreement is reproduced in full to illustrate the terms to which the boy voluntarily bound himself. While probably not unusual for the period, these terms speak for themselves.

---

[1] Memoir prepared by Philip H. Carlin, Scott B. Lilly, and Henry J. Sherman, Members, Am. Soc. C. E.

"This Indenture,

"Witnesseth, that Charles H. Stevens being a minor, and of the age of 12⅓ years, by and with the consent of his mother hath put himself, and by these presents, doth voluntarily, and of his own free will and accord, put himself Apprentice to T. Shaw, M. E., to learn the art and trade of Machinist business, and after the manner of an Apprentice to serve the said T. Shaw, M. E., until he shall have attained the age of twenty-one years, to wit: the 21st day of October in the year of our Lord one thousand eight hundred and ninety-six. During all which time the said Apprentice doth covenant and promise, that he will serve his master faithfully, ten hours each day—Sundays, Christmas day, and Fourth of July excepted—keep his secrets, and obey his lawful commands; that he will do him no damage himself, nor see it done by others, without giving him notice thereof—that he will not waste his goods, nor lend them unlawfully—that he will not contract matrimony within the said term—that he will not play at cards, dice, or any other unlawful game whereby his master may be injured—that he will neither buy nor sell, with his own goods or the goods of others, without license from his master—and that he will not absent himself day nor night from his master's service, without his leave—nor haunt ale houses, taverns or play-houses, but in all things behave himself as a faithful apprentice ought to do during the said term, and use his utmost endeavors to instruct other apprentices, when required. And the said master on his part, doth covenant and promise, that he will use the utmost of his endeavors to teach, or cause to be taught or instructed, the said Apprentice, in the art and trade of Machinist business, and will make allowance to his mother during said term, in lieu of sufficient meat, drink, clothing, lodging, washing, and all other necessaries fitting for an Apprentice, as follows:

$2.50 per week, for the 1st year; and $3.00 per week for the 2nd year
$3.50 per week for the 3rd year; and $4.00 per week for the 4th year
$4.50 per week for the 5th year; and $5.00 per week for the 6th year
$5.50 per week for the 7th year; and $6.00 per week for the Balance of the Term.

for every week in which said Apprentice shall be at work. In case of sickness, provided a Doctor's certificate be furnished for the time he is absent, the allowance shall not be deducted except in case of sickness and injuries brought on by his own imprudence. If a Doctor's certificate be not furnished, all allowance shall cease till said Apprentice resumes work. Should the said Apprentice, except in case of sickness, absent himself from work, without his master's permission, he shall forfeit at the rate of double the above wages for every working day in which he shall so absent himself. Should the said Apprentice, through idleness, negligence, or carelessness, neglect to perform his allotment of work, or fulfil it of inferior quality, or shall break any rule of the factory, he shall forfeit a just proportion of above allowance for such negligence or carelessness. Any compensation for overwork shall be subject to forfeiture for any breach of the order or discipline of the factory.

"And for the true performance of all and singular the covenants and agreements aforesaid, the said parties bind themselves each unto the other, firmly by these presents. In witness whereof, the said parties have interchangeably set their hands and seals hereunto. Dated the 27th day of February in the year of our Lord one thousand eight hundred and eight-eight.

Sealed and delivered before me, the Subscriber, Cora I. Shaw
Thomas Shaw, M. E.
Charlie H. Stevens
Mrs. K. M. Stevens"

After completing his apprenticeship, Mr. Stevens served as draftsman with the Reading Railway Company for one and one-half years and then, in 1900, began his long career with the City of Philadelphia, initially as bridge draftsman in the Bureau of Surveys. With the exception of four years, from 1903 to 1907, which he spent with the Philadelphia Rapid Transit Company (later the Philadelphia Transportation Company) on designs for the Market Street Subway-Elevated Railway, Mr. Stevens was to continue in the service of the city in various capacities until 1940—a period of more than thirty-seven years.

During the years of his apprenticeship and early engineering employment, Mr. Stevens made good use of every opportunity to obtain the education of which he had been deprived by the circumstances of early life. He attended evening classes at several technical schools during this period, and also pursued extensive studies at home throughout his early life. The result was that, as his responsibilities increased, he was always able to supplement his practical engineering knowledge with the theoretical background necessary for application to new problems. In this connection, although Mr. Stevens was preeminent in administrative work rather than in technical design, he nevertheless displayed unusual ability in analyzing design problems.

Mr. Stevens returned to the Bureau of Surveys in 1907 as assistant engineer in the Grade Crossing Division, in charge of design, preparation of plans and specifications, and estimates of cost of construction. The principal activity of the division at that time was elevation of the tracks of the Philadelphia and Reading Railway Company (later the Reading Company) to abolish grade crossings between Spring Garden Street and Broad Street, between 16th Street and Wayne Junction, and along the Richmond Branch from B Street to Richmond Street.

On completion of this work in 1913, Mr. Stevens was employed for four months in superintending the installation of a system of high-pressure fire mains in the northeast section of the city.

At about this time there was a growing realization of the advantages of high-speed transit facilities over the surface trolley system which prior to 1907 had provided all public transportation service in Philadelphia. Although at that time the passenger automobile was just coming into use, it had already created a certain amount of dissatisfaction with the comparatively slow surface system. Various areas of the city, particularly the northern and northeastern sections, were in need of faster service, and the phenomenal growth of the 69th Street section at the western terminus of the Market Street Subway-Elevated Railway was not without effect on the imagination of real-estate operators in other areas.

All these factors contributed to a growing demand for additional high-speed facilities. At the same time it became evident that the Philadelphia Rapid Transit Company was not in a position to finance further extensive construction work, and municipal financing would be required.

In view of this situation, the city council on May 13, 1912, appointed A. Merritt Taylor as transit commissioner to study the matter, and began the legal steps necessary to acquire authority to construct and own transit facilities. The engineering firm of Ford, Bacon and Davis was retained in a consulting capacity for the transit investigation. On July 14, 1913, Mr. Taylor submitted to Rudolph Blankenburg, then Mayor of Philadelphia, a comprehensive high-speed transit program calling for construction of the Frankford Elevated Railway and the Broad Street Subway, among other projects. These recommendations (although with later modifications) were destined to provide the foundation for Philadelphia's high-speed transit construction program.

Meanwhile the necessary enabling legislation had been passed at Harrisburg, and on June 26, 1913, the city council created a Department of City Transit, to have charge, control, and management of the transit facilities of the city. Organization of the department began immediately, and on July 1, 1913, Charles H. Stevens was transferred to the department as chief draftsman. From that time on, the life of Mr. Stevens is in a very real sense the history of high-speed transportation development in Philadelphia.

The first project undertaken by the new department was the design and construction of the Frankford Elevated Railway. This is a two-track structure extending from Front and Arch streets in Front Street, Kensington Avenue, and Frankford Avenue to Bridge Street in Frankford, a distance of 6.4 miles. In his capacity as chief draftsman, Mr. Stevens supervised preparation of plans and specifications for the entire structure and for its equipment.

During the period from 1913 to 1918, design work also went forward for various parts of the Broad Street Subway, including sections under, and adjacent to, City Hall, and several construction contracts were awarded. However, progress was slow. The entry of the United States into World War I prevented the award of further contracts after April, 1917, and finally, in July, 1918, forced termination of all remaining construction activities.

However, during the war and early postwar years, the department completed its designs for the Frankford Elevated Railway and Bustleton Surface Line. The Frankford elevated line, including terminal yard, three electric substations, and one hundred cars, cost about $15,000,000. Construction was delayed by World War I, but the line was finally completed by the department and was opened to service in November, 1922, by the Philadelphia Rapid Transit Company, lessee and operator of all city-owned lines. Unusual design features of the Frankford elevated line are the passenger station buildings, which house the stairs to relieve the sidewalks of obstruction, and the cruciform-bent steel structure of the elevated in Frankford, which frees the narrow sidewalks of column and pole obstructions. The Bustleton surface line, a much smaller project completed at about the same time, is a $700,000 single-track surface-car feeder extending from Frankford Avenue and Bridge Street via Bustleton Pike to Byberry.

Little new work could be undertaken during the period from 1918 to 1923 because basic questions had arisen as to the adequacy of several of the remaining projects as originally proposed, and in 1923 a transit advisory board appointed by J. Hampton Moore, then Mayor of Philadelphia, recommended extensive modifications to these projects. Additional changes were recommended by a councilmanic transit commission during the course of the year, and, at the November, 1923, general election, the voters approved the projects in their revised form and voted funds to reopen the work.

The department once again had a definite program and sufficient funds with which to proceed. However, its staff had shrunk to a very small size in the meantime, and in March, 1924, Mr. Stevens was appointed engineer of design with the task of assembling an adequate staff of engineers and draftsmen for the design of the projects as authorized.

The design staff was quickly expanded, and the department went ahead with plans and specifications for the Broad Street Subway north of Stiles Street. This work was completed and the entire section between Stiles Street and Courtland Street was placed under contract during 1924. In 1925, contracts were awarded for the remaining sections of the North Broad Street Subway.

The design work continued at a rapid rate under Mr. Stevens' direction, and, by the end of 1927, plans and specifications had been prepared and contracts let for the Fern Rock Terminal Yard, with its service buildings, and for the subway under South Broad Street north of Kater Street (near South Street).

Designs for the substation buildings necessary to provide direct current for subway operation were next completed. Construction work went on without the earlier delays, and in September, 1928, the North Broad Street Subway was opened for operation. Service was extended south to Kater Street in April, 1930.

The sections of the Broad Street Subway completed and opened for service during Mr. Stevens' incumbency as engineer of design consist of 6½ miles of four-track structure and ¼ mile of two-track structure at the south end. Only two tracks are operated. The total cost of this work, including terminal yard and service buildings, four electric substations, and one hundred and fifty cars, was about $110,000,000. The most advanced designs were utilized throughout the work. Station platforms are 550 ft long, permitting the operation of eight-car trains. Some interesting and difficult problems were involved in the work, particularly in the underpinning of City Hall, a massive masonry building with walls up to 12 ft thick and with foundations of uncertain character in some places.

In 1928 the department began work on plans and specifications for the relocation of the Market Street Subway tracks at City Hall in connection with the City Hall Concourse, and for the construction of the Ridge Avenue Branch of the Broad Street Subway.

When the Market Street Subway was constructed, both high-speed and subway-surface tracks had been detoured around City Hall to avoid the necessity for underpinning that structure, but this arrangement added appreciably to the time and cost of operating cars between the 13th Street and 15th Street stations. The new designs overcame the more serious of these conditions by providing a direct east-west route under City Hall for the high-speed trains. The subway-surface tracks were then relocated in the space previously occupied by the high-speed tracks, and the areas thus cleared were renovated to provide an underground concourse for pedestrians.

The subway in Ridge Avenue was planned to extend from a connection with the Broad Street Subway at Fairmount Avenue, in Ridge Avenue, Eighth Street, and Locust Street to 18th and Locust streets, and ultimately to West Philadelphia. Because of a shortage of funds, only that section of the line north of Ranstead Street (near Market Street) has actually been completed and put into operation (December, 1932), although subway construction was continued west to 18th Street. The cost of constructing the entire 2.28 miles of this two-track subway was $17,300,000.

In 1929 plans and specifications were begun under Mr. Stevens' direction for the first section of the two-track Market Street Subway Extension, from 24th Street to 32d Street. This section included a tunnel under the Schuylkill River designed as an integral part of the foundations for a new two-arch highway bridge to be constructed over the river on the line of Market Street. The subway was planned to extend ultimately from 22d Street to about 46th Street, permitting removal of the existing elevated structure between those points, but financial difficulties intervened. The work was closed up in 1932, after completion of the 24th Street-32d Street section at a cost of $6,900,000. The river crossing presented some difficulties because of the condition of the soil under the river, where both rock and a deep layer of mud were encountered.

In the midst of the City Hall Concourse and Ridge Avenue subway work, the department suffered the loss by death of its very able chief engineer, Frank R. Fisher. Mr. Stevens had been directing the design work with speed, effectiveness, and a high degree of technical competence, and in recognition of his ability he was appointed chief engineer, succeeding Mr. Fisher in August, 1930.

The economic depression of the 1930's curtailed further work on the Locust Street Subway and Market Street Subway Extension, but permitted work at a slow pace on the two-track South Broad Street Subway. The section of this line between Kater Street and Snyder Avenue was completed at a cost of about $8,000,000 and was put into operation in September, 1938, bringing to an end, for the time, construction of high-speed facilities.

Mr. Stevens retired as chief engineer of the Department of City Transit in January, 1940. During his twenty-seven years of service with the Department of City Transit, he had been in charge of designs for, and construction of, many kinds and types of work. As chief engineer, he directed not only the actual design and construction of subway structures with all the attendant problems of underpinning and protecting existing buildings along the streets and the underground service structures under these and intersecting streets, but also the installation of services and equipment to provide a completed system, ready for operation when leased by the operating company. His work included the installation of trackage, complete automatic signal systems, and automatic train control, as well as station finish and controls for the collection of fares. Further technical problems involved were design and construction of substation buildings, transformers, converters, rectifiers, and all appurtenant equipment required to transform and convert 13,200-v alternating current to 600-v direct current; installation of underground cables for distribution of power and for electric light and telephone service; lighting of subways and stations; and installation of complete subway drainage systems with sumps from which the accumulated water is pumped into the city sewerage system above the roof of the subway. Under his able leadership, the design and construction of passenger cars incorporated many new features which contributed both to ease and economy of operation, and to the safety of passengers and operating crews; and terminal yards and shop buildings were developed and constructed with facilities for the storage and maintenance of cars particularly adapted to the problems of operation of high-speed transit lines.

Preparations by the federal government for the approaching war emergency drew Charles H. Stevens back into public service in January, 1941, when he was appointed chief zone engineer, Construction Division, Quartermaster Corps, War Department, for Zone III, comprising Pennsylvania, Maryland, and Virginia, with headquarters in Baltimore, Md. In this capacity, he supervised the work of architect-engineers and contractors throughout the tristate area in connection with the construction of cantonments, quartermaster and ordnance depots, airfields, and lease-lend warehouses, among other structures. The cost of such work done under Mr. Stevens' supervision amounted to several hundred million dollars.

Upon completion of the duties assigned too him, Mr. Stevens resigned from this service on April 2, 1942. From then until the time of his death, Mr. Stevens was not very active professionally because of his health. He had expended a tremendous amount of mental and physical energy in planning construction for the Quartermaster Corps. However, he was called upon from time to time as a consultant on transportation and on subway and subsurface construction problems. Although he had enjoyed excellent health until about 1940, a heart condition was developing which on more than one occasion prostrated him for short periods. His heavy responsibilities as chief engineer of the Philadelphia Department of City Transit and as chief zone engineer for the Constructing Quartermaster undoubtedly contributed to the failure of his health. However, he continued to give his time without stint to these services and, with characteristic determination, was preparing to undertake new responsibilities shortly before his final illness. This began on February 2, 1944, and on the following day he died without regaining consciousness.

Mr. Stevens was active in the affairs of the Society for many years. He was particularly active in the Philadelphia Section of the Society, which he served with distinction as Secretary-Treasurer from 1922 to 1924, as President in 1924–1925, and as chairman of the Board of Trustees of the Richard L. Humphrey Memorial Fund (which he largely helped to create) from 1932 until his death. From 1930 to 1932, he served as Director of the Society for District 4, in which capacity he was a member of the Committee on Publications that established *Civil Engineering*. In 1941 and 1942 he was Vice-President of the Society for Zone II, and to this office also he devoted much time and effort.

As a result of Mr. Stevens' long experience in transportation and subway work, he became recognized as an expert in the design and construction of rapid-transit lines and equipment. His active life was rich in experiences covering a wide field of engineering, and was also rich in associations with civil engineers of such ability and prominence as George S. Webster,[2] Past-President, Am. Soc. C. E.; and C. E. Myers,[3] William S. Twining,[4] Samuel T. Wagner,[5] and Henry H. Quimby, Members, Am. Soc. C. E.

In addition to his activities in the Society, Mr. Stevens was a charter member of the Society of Municipal Engineers of Philadelphia, which he served at various times as secretary-treasurer and as president. In 1925 this society conferred upon him its medal for twenty years of meritorious service to the City of Philadelphia. He was also a past director and past vice-president of the Engineers Club of Philadelphia, a member of the American Society for Testing Materials, and a former member of the American Concrete Institute.

Throughout a long and unusually active business life, Mr. Stevens found time for many church activities. He was an active member of the Methodist Church throughout adult life, and at the time of his death was president of the Board of Trustees of the Mount Carmel Methodist Church.

Integrity and sincerity were outstanding characteristics of Charles H. Stevens. Another was the determination with which he pushed forward at all times toward his goal, whether this was a technical problem which required solution or a more personal matter. This determination sometimes expressed itself in a certain ruthlessness toward those who failed to agree with him and even toward those who expressed divergent opinions. However, none could doubt the sincerity of Mr. Stevens' belief in the rectitude of his course, or the integrity of his character.

Mr. Stevens was married in 1904 to Emily E. James of Philadelphia, and had two sons and a daughter. He is survived by his widow and sons (Charles J. Stevens, Assoc. M. Am. Soc. C. E., and Henry B. Stevens, an architect).

Mr. Stevens was elected an Associate Member of the American Society of Civil Engineers on May 6, 1914, and a Member on January 20, 1920.

WILLARD WILBERFORCE STONE, M. Am. Soc. C. E.[1]

DIED FEBRUARY 11, 1944

Willard Wilberforce Stone was born in Brookline, Mass., on October 23, 1873. His father, Grafton Willard Stone, was born in Newton, Mass., on September 22, 1835, and died in Brookline on March 17, 1879. His mother, Betsey Carpenter (Babbitt) Stone, was born in Berkley, Mass., on August 31, 1843, and died in Berkley on August 4, 1903. Grafton Willard Stone and Betsey Carpenter Babbitt were married in Berkley on November 16, 1865.

[1] Memoir prepared by Charles D. Thomas, M. Am. Soc. C. E., with the assistance of Florence H. Stone, Taunton, Mass.

Mr. Stone was descended from a long line of ancestors prominent in colonial times and in England before coming to the United States. His father's family were well known:[2]

> "The Stone family is among the forty-nine best families selected by the American Historical-Genealogical Society for whom the society has published family histories during the past few years. The Stone family has been prominent in the British Empire and in United States, its members have played important roles in war and in peace."

In "Simon Stone Genealogy"[3] there is a family tree of the Stone family from Walter Atte Stone "born probably as early as 1285 in the reign of Edward I," to Simon Stone with a note under the latter name "went to America." Other excerpts from this book may be of interest:

> "Deacon Simon Stone and his brother Deacon Gregory Stone pioneers in New England in 1635 * * * descended mainly from the old Anglo-Saxon and Danish stock conquered by the Normans * * * lived in Essex and adjoining Suffolk from a period in Saxon time long prior to the Norman Conquest. The earliest mention that has been found of the name there is in 1302 under the form of Atte Stone and this form continued in use until about 1450 when the 'Atte' disappears. It therefore seems obvious that this particular Stone family derived their name from the fact that a remote ancestor in the thirteenth century assumed or was termed 'Atte Stone' from residing at or near some prominent stone landmark in the region."
>
> "On April 29, 1904 a beautiful stained glass window in memory of Simon and Gregory Stone was unveiled and dedicated at Great Bromley, Essex, England, funds having been raised among their descendants in America. Deacon Gregory and Deacon Simon Stone * * * were baptized and four generations of their ancestors were christened there and had sepulture in its church yard."

The records show that through several generations in the United States the Stone family has furnished officers in the militia, town officials, representatives to the General Court of Massachusetts, many deacons of the church, and a councilor of Massachusetts.

On his mother's side, Mr. Stone also had illustrious ancestors.[4] The Babbitt family was descended from Edward Bobit who came to the United States in 1638, settled in Berkley (then a part of Taunton, Mass.), purchased land there in 1652, became one of the proprietors in the "Bloomerie" as the ancient Iron Works of Taunton were named, was married to Sarah Tarne in 1654, and was killed by the Indians in June, 1675. The Babbitt family has been prominent in the localities where its members have lived, furnishing officers of the militia, town officials, members of committees for settling disputes with the Indians, and a representative to the General Court at Boston, Mass., in 1787.

---

[2] "Stone Family Records," by J. Montgomery Seaver, Genealogical Research and Publishing Co., Philadelphia, Pa., 1929.

[3] "Simon Stone Genealogy," by J. Gardner Bartlett, published for the Stone Family Assn. of Boston, Mass., Pinkham Press, Boston, 1926.

[4] "The Babbitt Family History," by William Bradford Browne, published for the Babbitt Family Assn. of Taunton, Mass., C. A. Hack & Sons, Taunton, 1912.

Grafton Stone, Mr. Stone's father, was in business in Newton, until about the time of his marriage when he moved to Brookline, where all his four children—Carrie M., Grafton Edgar, Willard Wilberforce, and Florence Helen—were born. After her husband's death, Betsey Stone and her two surviving children, Willard and Florence, returned to Berkley, her native town. (Carrie Stone died on March 11, 1879, and Grafton Edgar Stone died on January 4, 1873.)

From the time he was about six years old, Mr. Stone was brought up and educated in a locality rich in historic events and folklore. The house in which he lived was the old Babbitt homestead built in Berkley on the bank of the Taunton River by his maternal grandfather, John Dean Babbitt, in 1836. A few miles north, up the river in Massachusetts, was the flourishing iron manufacturing city of Taunton and to the east were historic Plymouth and Cape Cod. Mr. Stone attended the local public schools and the high school at Taunton from which he was graduated in 1893.

After graduation from high school, Mr. Stone was employed in the Engineering Department of the City of Taunton until September, 1896, as rodman, instrumentman, inspector of construction on a $400,000 sewer system, and assistant engineer in charge of field party on surveys for sewer, street, and paving work. The City of Taunton at that time adopted and started construction on a comprehensive system of sewers which, with extensions, is still in use. He was also instrumentman on the layout of the Taunton-Fall River Street Railway.

Mr. Stone's associates in the office of the city engineer heard many stories of early historical events along the Taunton River and on Cape Cod. One day in the spring, a group of engineers visited East Taunton, Mass., and enjoyed the remarkable sight of herring running up the Taunton River and passing through the fishways at the dam. Below the dam the fish were so thick that it appeared as if one could walk across the river on a floor of fish.

From September, 1896, to June, 1900, Mr. Stone attended Massachusetts Institute of Technology in Boston, being graduated with the degree of Bachelor of Science in Civil Engineering. From August, 1900, until his death, he held the following interesting positions:

August, 1900, to July, 1902—Draftsman and designer on a sewerage disposal system in Washington, D. C., designing sewers up to 18 ft in diameter, cofferdams, tide gates, outfall sewers, suction and discharge conduits, foundations, and accessory structures for a $1,000,000 sewerage pumping station.

July, 1902, to February, 1906—Assistant engineer for the State of New York acting as resident engineer in charge of construction of roads and bridges (seven contracts) in Onondaga County, among which were the Fabius-Apulia Road and the Skaneateles East Lake Road.

February, 1906, to June, 1913—Assistant engineer, Board of Water Supply, City of New York, N. Y., in charge of topographical surveys and field location of aqueduct; senior assistant engineer in charge of two aqueduct contracts totaling $1,000,000 (one, a $250,000 contract for a steel pipe line 9½ ft in diameter, and the other, a $750,000 cut-and-cover contract); engineering expert, Newburgh Division, Board of Water Supply of New York City, on the appraisal of property taken by the city for construction of the aqueduct (about 20 miles long with property claims amounting to about $2,500,000); and consulting engineer on water supply for Walden, N. Y.

June, 1913, to April, 1914—Senior highway engineer for the United States Office of Public Roads at Washington, D. C., in charge of surveys, designs, estimates of cost, and construction of roads and bridges in Virginia and North Carolina.

April, 1914, to April, 1916—Assistant engineer, New York State Highway Commission, in charge of designs, estimates of cost, and construction of brick, bituminous, and concrete highways costing $800,000. (Mr. Stone returned to New York State because his health was poor in the hot climate of the South.)

April, 1916, to July, 1917—Road engineer for the Portland Cement Association, in charge of designs, estimates of cost, and construction of concrete highways costing $2,000,000.

July to December, 1917—Engineer for Frazier Brace and Company at the Federal Shipyard in Kearny, N. J., in charge of making designs for deepening and widening the Hackensack River at the plant and designing docks.

January, 1918, to November, 1919—Engineer with Snare and Triest Company, construction engineers on the construction of Raritan Arsenal at Metuchen, N. J., in charge of building storm and sanitary sewers, a sewage disposal plant, and a water-works system (a $900,000 project).

December, 1920, to June, 1921—Engineer assistant, Valuation Department, Baltimore and Ohio Railroad Company, in charge of field work in Pennsylvania and Illinois, inventorying special structures.

July, 1921, to September, 1922—Resident engineer for Fuller and McClintock, sanitation engineers, in charge of construction of sewer extensions and pumping stations at Glen Cove, N. Y. (a $250,000 project); and in charge of designing works for additional water supply at Newburgh, N. Y., including earth and masonry dams, gatehouses, pipe lines, and special structures (a $200,000 project).

September, 1922, to February 11, 1944—On the engineering force in the Office of Nassau County Engineer (which became, on January 1, 1938, the Department of Public Works), in charge of an engineering party in the Division of Highways. In this capacity, Mr. Stone supervised necessary investigations and highway surveys and also office work. He plotted surveys, prepared construction drawings and plans for acquisition of the property necessary to locate and widen arterial streets in Nassau County, arranged the field work, and supervised the construction of the highways. Among the numerous arterial highways in Nassau County under his direction were parts of Merrick Road, Hempstead Avenue from Lynbrook, N. Y., to Hempstead, N. Y., Clinton Road, and the Horse Brook improvement. He designed and had charge of construction of the bridge that carries Atlantic Avenue over Milburn Creek at Freeport, N. Y.

Mr. Stone was very accurate in designing and checking engineering work and his associates considered him the best mathematician in the office. Many men in executive positions have profited greatly from being with Mr. Stone. He played an important part in the engineering department while Nassau County was developing from a farming community to a metropolitan area. Because of an increase in population from approximately 150,000 in 1920 to about 450,000 in 1944, which caused greater motor vehicle traffic, 400 miles of highways had to be straightened, widened, and reconstructed. He was well liked by all his associates, many of whom sought his advice on engineering subjects. Henry A. Van Alstyne, M. Am. Soc. C. E., a former state engineer of New York, wrote on December 11, 1917:

> "I have known Mr. Stone for over fifteen years. He is a man of high character, good habits and excellent reputation. * * * He is a capable, reliable, energetic and trustworthy engineer."

Mr. Stone was 6 ft 6 in. tall and during his early manhood was thin but later he became heavier and at one time weighed about 225 lb. He was a very sociable man, and attended the meetings of his club and of engineering societies. He attended the Carpenter Memorial Methodist Church at Glen Cove, he participated in church activities, and purchased and presented to the church a war service flag. He made many friends and always remembered the smallest details about the people he knew. In spite of his sociable nature and his grace in talking with the ladies, he never married. During the last twenty-two years of his life, his tall stately form has been a familiar sight wherever Nassau County highway work was in progress.

For about three months before his death at the Nassau Hospital in Mineola, N. Y., Mr. Stone was in poor health. He was buried in Newton, Mass. A sister, Florence H. Stone, survives him.

Mr. Stone belonged to the Republican Club of Glen Cove, and the Society of American Military Engineers. He was a registered professional engineer and land surveyor in New York State.

Mr. Stone was elected an Associate Member of the American Society of Civil Engineers on February 7, 1906, and a Member on January 19, 1923.

MERTON ROGERS SUMNER, M. Am. Soc. C. E.[1]

Died November 5, 1943

Merton Rogers Sumner was born at South Paris, Me., on June 11, 1886, the son of R. C. and Lillian Sumner.

After being graduated from the University of Maine, at Orono, with the degree of Bachelor of Science in Civil Engineering, he was employed by the Fort Worth-Cleborne Interurban Railroad Company on construction at Fort

---

[1] Memoir prepared by A. C. Ackenheil, M. Am. Soc. C. E.

Worth, Tex. He then worked for Stone and Webster Engineering Corporation on hydroelectric development in California. Returning to the University of Maine for further study, he received the degree of Civil Engineer in 1918.

Resuming his career, Mr. Sumner then was in charge of design for Fred T. Ley and Company and the Fuller Industrial Engineering Company on the construction of the U. S. Bomb Loading Plant at Rockwell Park, Del. After this engagement, he was employed by the Byllesby Engineering Corporation, advancing to general superintendent of construction for the Pittsburgh (Pa.) district. While with this company he contributed numerous articles to the technical press. He also gave lectures on advanced economics at the University of Pittsburgh, in Pittsburgh.

When the United States entered World War II, Mr. Sumner became project engineer for the John F. Casey Company on the construction of the Neville Island Parkway for the Navy Department. When this work was completed, he became associated with the Defense Plant Corporation as office engineer in Pittsburgh.

Affable and of an engaging manner, Mr. Sumner had many friends who mourn his passing. His engineering ability was of a very high standard, and he had the respect and confidence of his associates.

He is survived by his widow and three children, Virginia, Hugh, and Paul. The boys are both serving in the armed forces of the United States.

Mr. Sumner was elected an Associate Member of the American Society of Civil Engineers on May 13, 1918, and a Member on March 8, 1921.

JOHN CALVIN SWEENEY, M. Am. Soc. C. E.[1]

DIED AUGUST 16, 1944

John Calvin Sweeney, the son of John and Mattie (Bomar) Sweeney, was born in Paris, Tenn., on August 9, 1885. His father was a prominent Paris lawyer and at one time a federal judge in the Philippine Islands. John received his early education in the Paris public schools, was graduated from the United States Naval Academy at Annapolis, Md., in 1905, and completed a graduate course at the Massachusetts Institute of Technology in Boston in 1910.

He then began a most unusual and varied career in engineering and construction of railroads, hydroelectric developments, buildings, dams, shipyards, and ports and terminals. His career culminated in his last position as resident manager in charge of naval base construction at Trinidad, B.W.I., for the James Stewart Associates. His professional work took him to most parts of the United States and Canada and to some foreign countries.

In 1910 he went to Canada, as superintendent and chief engineer for William Carson, of Winnipeg, Man., for whom he designed and constructed hotels, post offices, railroad roundhouses, bridges, stations, and one hydroelectric station for the Canadian Pacific Railway. In 1912 he became chief engineer and manager for Michael Connolly in Montreal, Que., in charge of harbor works and the breakwater at St. John, N.B.; piers at Three Rivers, Que., and at Goderich, Ont.; a paper mill and hydroelectric development at St. Raymond, Que.; and water works at Quebec.

---

[1] Memoir prepared by Gardner S. Gould, M. Am. Soc. C. E.

In 1914 he became district and supervising engineer for the Department of Public Works of Canada, in charge of design and supervision of all public works in western Canada, including the lock and dam at St. Andrews; flood control works on the Red and Assiniboine rivers; protection work at the mouth of the Red River; land reclamation near Lake Manitoba in the Province of Manitoba; and shipways and yard at Selkirk; together with dredging and bridges over navigable rivers, buildings, etc., which came under the jurisdiction of the Department. Late in 1914 he was employed by the Toronto (Ont.) Harbor Commission on a harbor development which was under contract to the Canadian Stewart Company. Subsequently he resigned his position with the Toronto Harbor Commission and joined the Stewart organization. He later supervised war emergency work, enlarging harbor and pier facilities at St. John.

When the United States entered World War I in 1917, he returned to the United States and, as engineer for James Stewart and Company, worked on cantonment construction at Little Rock, Ark. (Camp Pike); Fayetteville, N. C. (Camp Bragg); Leon Springs, Tex.; and Fort Douglas, Utah. In this same assignment were included the Naval Operating Base at Sewall's Point, Va.; bulkheads at Hampton Roads, Va.; a seaplane base at Bayside, L. I., N. Y.; and a housing development at Erie, Pa.

In 1918 he returned to Canada for the Canadian Stewart Company to construct a plant and dam for the Abitibi Paper and Power Company and also various buildings for General Motors of Canada, Fisher Body Company, and Burroughs Adding Machine Company.

At this time, Mr. Sweeney suffered his first attack of pulmonary tuberculosis, which forced him to leave Canada and go to Saranac Lake, N. Y., for treatment. He continued, however, to act as advisory engineer for James Stewart and Company on New York State Barge Canal contracts and for the Standard Oil, Gulf Refining, and Humble oil companies on plants, buildings and piers.

In 1924 Mr. Sweeney opened his own office as a consulting engineer and, during the next ten years, was actively engaged on diversified projects for many clients, including Cuban highways for James Stewart and Company; a hydroelectric development on the Deschutes River in Oregon; harbor developments and a paper mill at Vancouver, B. C., Canada; various bond issues for E. H. Rollins and Company; harbor and dredging projects in Canada for the Canadian Dredging Company; dams, power developments, dredging, and other improvements for Paul Smith Electric Power and Railroad Company and the International Paper Company; and buildings and improvements at the Lake Placid (N. Y.) Club. He made an examination and report on the principal hydroelectric dams and developments in the United States for F. W. Stehr and W. D. Ross.

In 1928 he moved to California, continuing his consulting practice there. He acted for Merritt, Chapman and Scott on piers and harbor developments and on a proposed project in Mexico; for the Continental Oil Company and for Republic Steel on piers and other structures; and for the Rohl-Connolly Company on the El Capitan Dam, a rock-fill and hydroelectric-fill structure. After the 1933 earthquake, Mr. Sweeney went to Long Beach and volunteered his services as inspector. These were accepted and he took charge of inspection forces until September, when reconstruction was practically complete. For this work, he received the thanks of the city manager and council. Following this, in continuation of his work on earthquake damage, he made a general survey and damage appraisal for the J. V. McNeil Company and an investigation and report of the earthquake in collaboration with Prof. R. R. Martel, M. Am. Soc. C. E. He also served the United States Coast and Geodetic Survey in an advisory capacity. He was consultant on San Gabriel Dam No. 1 in California; but, as he did not concur in the design and methods adopted, he resigned in 1934. His opinions were later upheld and engineering forces of the Los Angeles Flood Control District were reorganized, construction halted, and the design changed to meet his recommendations.

In 1935 Mr. Sweeney returned to the Atlantic coast and was employed by the Corps of Engineers of the United States Army on the Passamaquoddy (Maine) tidal power project. He made weather and current studies and reports and drew up recommendations for proposed construction equipment and methods, power requirements, etc. In August, 1935, he was placed in charge of all foundation explorations and designed and built the special equipment necessitated by the extreme depths involved and by the severe tidal and weather conditions. All this was successfully accomplished at a cost much below the appropriations. He was then appointed senior superintendent of construction in charge of all permanent work; and, before the Passamaquoddy project was closed, he had opened several quarries, built railroads, and constructed three minor dams. He was transferred to Fitchburg, Mass., as engineer in charge —for the Corps of Engineers—of a $1,800,000 flood control project, handling all administrative, as well as engineering, features of the work.

In August, 1937, Mr. Sweeney returned to Tennessee, in the hope that he could remain there permanently. He entered very actively into water and power work in western Tennessee, particularly in Paris. At the request of the municipal government, he organized all communities served by the Kentucky-Tennessee Light and Power Company into a unit which he represented in negotiations resulting in the purchase of all the properties of the company. He was asked to assume the management of the Paris Electric and Water System and accepted the position. He put the system on an exceptionally profitable basis during its first year of operation, at the same time effecting complete rehabilitation with the aid of a grant from the Public Works Administration.

Soon after the beginning of World War II, Mr. Sweeney found that he would not be permitted to end his days peacefully in Tennessee. In late 1940, when the great need of war shipping became evident and the inadequacy of shipyards was realized, he was called to take charge of the construction of the new yard for the Todd-Bath Corporation at South Portland, Me. This was the first large-scale instance on the east coast of building ships in prepared basins, floating them out as soon as they would float, and completing them afloat, thus permitting a quicker turnover than is possible on the customary sliding ways. Mr. Sweeney began this work in the early part of a New England winter and had most of the area down to grade and much of the side-walls completed by April. Hulls were under construction in July. The Atlantic Ocean was on one long side of the project and a difficult ground-water condition existed ashore; yet he handled the water problem so skilfully that, when the writer visited the job in April, the bottom of the excavation was drier than the surrounding uplands.

Late in 1941, soon after he left Portland, Me., Mr. Sweeney was asked by James Stewart Associates, who had been awarded the contract for the construction of the Trinidad and British Guiana naval air stations, to go to Trinidad as resident manager. Although the project in Trinidad began as a naval air base, it was soon enlarged to an operating and repair base for both air and surface ships. Mr. Sweeney's health had been poor for several years; and, although he fully realized that his illness would probably be aggravated by living in the tropics, he unhesitatingly took the job. With the help of a nucleus of extremely able superintendents and foremen, he welded together a most efficient organization and succeeded in completing the work and its great additions so rapidly and in such a manner that, in March, 1943, the company was awarded the Army-Navy "E." As in the case of most bases built in foreign lands, the contractors had to depend on a nucleus of American labor in key and skilled positions, using native labor to the greatest extent possible elsewhere. Mr. Sweeney was notably successful in the adaptation, training, and handling of native labor on this job, and the efficiency of this labor far exceeded expectations. Mr. Sweeney displayed great ingenuity in the use of makeshifts—methods, equipment, and materials—necessitated by the isolation of the job from ordinary sources of supply and by the lack of shipping facilities.

Mr. Sweeney's exertions, combined with the effects of the tropical climate, proved too much for his impaired health. Early in 1943, he suffered his third attack of tuberculosis, aggravated by other ills, and had to be brought back to the United States. He immediately entered a hospital in New York, N. Y., later going to the Oakville Sanatorium at Memphis, Tenn. He never recovered from this attack of illness and died at his home in Paris on August 16, 1944.

An appraisal of the qualities of a man like John Sweeney, whose life and activities were so varied and numerous, can only be a consensus of the opinions of the many men who knew and lived and worked with him. No man saw all of Mr. Sweeney. He was primarily a construction man—energetic, keenly practical, ingenious, and a hater of waste motion. However, these qualities were controlled by a sound engineering education and instinct. He was a driver, but always drove himself harder than he did his men. Impatient with, and somewhat contemptuous of, well-meaning regulations which tended to hamper progress, he never hesitated to break rules if he thought that, by so doing, better or quicker results could be attained.

Caustically critical of inefficiency and carelessness, he was generous in praise of good work and glad to give full credit to others. He always dominated any project with which he was connected, but in a way that won for him the admiration and respect of his co-workers. The writer had occasion to follow Mr. Sweeney on two of his last jobs and was amazed to note the almost reverential manner in which the field organization spoke of, and felt toward, him.

Mr. Sweeney was a keen judge of men, an excellent organizer, and wise in his ability to delegate authority. A Sweeney job was always a safe job and always a colorful one. The engineering profession and the construction industry have lost one of their ablest men in the death of John C. Sweeney.

He is survived by two sons: John C. Sweeney, III (in the "Seabees," U. S. Navy), and Richard H. Sweeney.

Mr. Sweeney was elected a Member of the American Society of Civil Engineers on December 22, 1930.

CHARLES MASON TALBERT, M. Am. Soc. C. E.[1]

DIED JANUARY 25, 1944

Charles Mason Talbert was born near Shelbyville, Shelby County, Ind. on September 27, 1870, the son of William and Amanda (Carter) Talbert. While still quite young he went with his parents to southwest Missouri where he grew up, developing a rugged pioneer constitution.

He received his education in the schools of southwestern Missouri and his training as a civil engineer at the University of Missouri in Columbia in the early nineties. Upon leaving the university, his first employment was with the Missouri River Commission for about three months. He then worked as leveler and recorder on levee work for the late Julius Pitzman,[2] M. Am. Soc. C. E., in St. Louis, Mo. In the spring of 1893 he went with the Mississippi River Commission as recorder on triangulation. He then acted, successively, as hydrographer, leveler, topographer, chief of party on surveys and discharge work, superintendent of a dredge and a dredging district, and general superintendent of dredging operations.

In 1902 he was employed by the Louisiana Purchase Exposition Company in charge of field work which included the construction of the Cascades on Art Hill in Forest Park. This was the most important landscape effect of the Exposition. During the year of the St. Louis Fair he was superintendent of building and installation of the exhibits in the Liberal Arts Building.

After the Fair he served as engineer for the president of the Board of

---

[1] Memoir prepared by John T. Garrett, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 88 (1925), p. 1426.

Public Improvements of St. Louis. During this time Mr. Talbert helped in the engineering work leading to the adoption of a new charter for the city. After it was adopted he was appointed to one of the most important positions created by it—that of Director of Streets and Sewers. He served in this capacity for sixteen years. During these years, since traffic was changing from horse-drawn vehicles to motor transportation, innovations were required such as a new type of pavement for the streets, the elimination of sharp curves, the marking out of safety zones, the installation of the first stop-and-go signs, and the designation of some of the narrower streets for one-way traffic. Because the coming of the motor cars caused a sharp increase in the number of traffic accidents on the streets and highways, new safety measures on the streets were necessary. As a result, the St. Louis Safety Council was organized in 1916. In 1920 Mr. Talbert was made president of the council. He later became an officer in the National Safety Council.

In 1919, seeing an opportunity in the insurance field, Mr. Talbert gave up public life and entered the insurance business, making a speciality of industrial buildings and engineering structures. He built up a substantial business in this line and remained in insurance until his death. He served as president of the St. Louis Fire Underwriters Association, later the Insurance Board of St. Louis, and for many years was a member of the City Plan Commission.

His interest in civic and municipal affairs prompted Mr. Talbert to become an early advocate and supporter of the Municipal Theater Association. At the time of his death he was a member of the association's board of directors and of the executive committee. In addition to these duties he handled the traffic problem during the yearly twelve-week opera season, in such a way that, even though there were thousands of cars to park every night, there was little or no delay in arriving or leaving the theater.

A man of high principles, sound judgment, and fine character, Mr. Talbert had the invaluable faculty of endearing himself to all those with whom he came in contact, both in a personal and business way. He possessed a refreshing sense of humor and had the ability to see the human comedy in routine matters about him. He liked people and they liked him. He kept himself well informed on all current subjects so that he was ready at all times to take part in any discussion. He was a great lover of books and had many rare and valuable editions on the shelves of his extensive library.

While he was superintendent of the Liberal Arts Building at the St. Louis World's Fair which housed extensive exhibits of oriental art, he came to know and admire oriental ideals and artistic skill. When the Fair was over and the exhibits were being removed, those in charge of the Oriental Exhibition presented him with a few samples of the art. These he took home, later to find that they were several hundred years old and admirable specimens of the Chinese art of that period. This started him on a hobby of collecting specimens of eastern art. Everywhere he traveled he visited out-of-the-way places and shops where he found many curious and rare pieces of oriental art. In his ivory collection, he had many old and valuable netsukes, small button-like appendages, intricately carved and used by the orientals since the Middle

Ages to hang from their girdles, attached to pipe cases, or medicine boxes, much the same as a watch fob.

All who knew Mr. Talbert well valued his friendship highly and found his companionship a pleasure and delight. As Hamlet said,

> "He was a man, take him for all in all,
> I shall not look upon his like again."

During World War II Mr. Talbert served as coordinator in the Office of Civilian Defense. He was a 32d degree Scottish Rite Mason and a member of the Mystic Shrine. He belonged to the Missouri Athletic Club and the Normandy Golf Club.

Mr. Talbert was married on April 12, 1899, to Mary Morse Davitt. He is survived by his widow and one son, William R.

Mr. Talbert was elected a Member of the American Society of Civil Engineers on March 4, 1914.

PETER GANSEVOORT TEN EYCK, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 2, 1944

Peter Gansevoort Ten Eyck, the son of Abraham Cuyler and Margaret Matilda (Haswell) Ten Eyck, was born on November 7, 1873, in Bethlehem, Albany County, N. Y.

Mr. Ten Eyck obtained his early education at the Albany (N. Y.) Boys Academy. In 1892 he entered Rensselaer Polytechnic Institute at Troy, N. Y., where he studied civil engineering for three years. His first employment was as engineer in charge of laying out and developing Beaver (later Lincoln) Park in Albany.

In 1896 Mr. Ten Eyck accepted a position with the Signal Department of the New York Central Railroad Company. After working as electrician, repair foreman, and supervisor of signals, he was promoted to signal engineer for the New York Central Railroad Company in 1902. In 1905 he resigned to become chief engineer of the Federal Railway Signal Company in North Albany. While he was with this company, Mr. Ten Eyck developed several signal devices, many of which are still in use. He became vice-president of the company in 1907. In 1908 he resigned to devote his time to real estate development.

For the next three years, in collaboration with his brother, he developed a tract of family acres into home sites. This property, a part of the old Gansevoort Farm in the southwestern quadrant of Albany, became a well-established residential section.

In 1912 Peter Ten Eyck began his long service to the public. In this year he was elected to the United States House of Representatives where he served until 1915. After a lapse of five years during which he was engaged in real estate development and as a consulting engineer, he was again elected to Congress, serving until 1923.

---

[1] Memoir prepared by John A. O'Connor, M. Am. Soc. C. E.

From 1923 to 1934 he was in the real estate business, practiced as a consulting engineer, and served as chairman of the Deeper Hudson River Commission. His unselfish interest in improving inland waterways, particularly the Hudson River, was manifest at all times. From 1923 to 1925 he supervised the compilation of a brief for the Port of Albany. The soundness of his work is evidenced by the construction of this port, which was begun in 1928. Mr. Ten Eyck was chairman of the Albany Port District Commission from 1928 to 1934 and had responsible charge of the construction of the Port of Albany.

Peter Ten Eyck was interested in many other fields than those of engineering and real estate. He belonged to the following learned and public societies: The American Society of Electrical Engineers, American Association of Signal Engineers, Albany Society of Engineers, Albany Realty Board, New York State Dairymen's Association, New York State Waterways Association, and numerous other societies and clubs. However, his true love and devotion were for the soil. For many years he successfully operated his "Indian Ladder Farms"—a dairy and fruit farm with considerable acreage in choice apples—in the Town of New Scotland (N. Y.). Mr. Ten Eyck had a keen interest in increasing the milk production of the Albany area, and did much pioneering work. Recognizing his leadership in this field, the Hon. Herbert H. Lehman, then Governor of New York State, appointed Mr. Ten Eyck director of the New York State Farm Bureau. In connection with agriculture, he was a member of the Board of Visitors for New York State School of Agriculture and president of the Capitol District Guernsey Breeders Association. He belonged to various other farm societies, and was one of the organizers of the American Farm Bureau Federation.

Mr. Ten Eyck had a fine personality. He was a dignified and courteous person with a host of friends who called him "Pete"; he liked club life and the society of men; had a certain flair for politics and a fine reputation as a public speaker. He gave unsparingly of his time in behalf of the many civic organizations in which he was interested.

On April 15, 1903, at Albany, he was married to Bertha F. Dedrick. He is survived by his widow and a son, Peter.

Mr. Ten Eyck was elected a Member of the American Society of Civil Engineers on February 19, 1934.

FRANK ELLSWORTH TRASK, M. Am. Soc. C. E.[1]

Died September 4, 1944

Frank Ellsworth Trask was born at Industry, Me., on July 26, 1863. He was the son of Nathaniel and Betsey Helen (Wills) Trask.

---

[1] Memoir prepared by William C. Hogoboom, Assoc. M. Am. Soc. C. E.

Mr. Trask was educated at Gould's Academy in Bethel, Me., and at the University of Maine in Orono, from which he received the degree of Bachelor of Civil Engineering in 1887 and the degree of Civil Engineer in 1890. He was a member of Phi Gamma Delta fraternity.

In 1887 Mr. Trask went to Southern California and engaged in general engineering at Ontario. This practice consisted largely of design, construction, and reports upon irrigation districts and municipal water systems, with some incidental work on land subdivision. In 1888 he was engineer for the San Antonio Heights Railway Company on the construction of eight miles of street railway.

During the 1890's, Mr. Trask was chief engineer for the San Antonio Water Company in connection with the $400,000 reconstruction and extension of an irrigation system and water supply. At the same time he was engineer for the Escondido (Calif.) Irrigation District, he designed and constructed a water works system for the City of Ontario, he made a report to the City of Pomona (Calif.) on municipal water supply, and he was employed as engineer by the Sycamore Water Development Company, the Pomona Orange Belt Irrigation District, and the Ontario Electric Company. For the last-named company, he designed and built eight miles of electric railway and a hydroelectric power plant.

After 1900 Mr. Trask served as consulting engineer for many municipalities, irrigation districts, and private companies on various types of water problems. This work involved construction of tunnels, dams, and reservoirs; reports and appraisals of water systems; and presentation of hydrographic data in court cases. Among the cities, irrigation districts, and companies which employed him as consulting engineer were: Whittier Water Company, Ojai Mutual Water Company, Consolidated Water Company, Arrowhead Reservoir and Power Company, Fontana Development Company, Mill Creek and Crafton Water Company, West Los Angeles Water Company, Union Hollywood Water Company, Rindge Company, Traders' Oil Company, Azusa Foothills Citrus Association, Mojave River Irrigation District, Santa Ana River Association, San Gabriel River Association, and the cities of Pomona, Escondido, Ontario, Covina, Redlands, and Huntington Park, Calif.; and Yuma, Ariz.

In 1933–1934, Mr. Trask served as California state engineer for the Public Works Administration (PWA), and in 1934–1935 he was a member of the Technical Board of Review of PWA at Washington, D. C. In 1935 he was retained as a permanent consulting engineer by the Los Angeles (Calif.) County Flood Control District.

For many years Mr. Trask was a leader in the development of underground waters in the Southwest through pumping and tunnel beds. He was the author of numerous papers on irrigation, and a contributor to engineering journals and textbooks. Having practiced in Southern California for more than fifty years, Mr. Trask was very well known in the engineering profession. He was admired and loved by the young engineers who knew him, because of his untiring efforts to help younger men and to advance the engineering profession in general.

On July 1, 1909, in Los Angeles, Mr. Trask was married to Carlotta Thornton. He is survived by three sons, George Harlan Trask, Olin Wills Trask, and Elwood Ellsworth Trask; a sister, Blanche (Mrs. Erwin Phillips); and three brothers, Loren Trask, Richard Trask, and Elmer Trask.

Mr. Trask was elected an Associate Member of the American Society of Civil Engineers on June 5, 1895, and a Member on January 2, 1901.

HARRY EDWARD TYRRELL, M. Am. Soc. C. E.[1]

DIED DECEMBER 5, 1943

Harry Edward Tyrrell was born in Philadelphia, Pa., on July 31, 1882, the son of Richard D. and Mary Emma (Sykes) Tyrrell. He received his education in Philadelphia public schools and the Technical High School, from which he was graduated in 1901.

Mr. Tyrrell was a self-educated man in many respects. He often spoke of the difficult course in mathematics and mechanics at the Northeast Manual School, in which he learned the first rudiments of engineering. He served an apprenticeship in the Pencoyd (Pa.) Plant of the American Bridge Company in 1902. Later his background was broadened by experience in minor capacities with the West India Construction Company, Norfolk and Western Railway Company, Bell Telephone Company, Pennsylvania Railroad Company, and Philadelphia and Reading Railway Company. In 1906 he was employed by the engineering department of the Southern Railway Company. His promotion was rapid, and in July, 1915, he became engineer, maintenance of way, in charge of the Western District of the Southern Railway Company, with offices at St. Louis, Mo. He was appointed chief engineer, maintenance of way and structures, for the Central Lines of the Southern Railway System on August 1, 1934, continuing in this position until his death.

Mr. Tyrrell had an unusual interest in his work, and was very successful. He was a resident of St. Louis for nineteen years, was active in the Engineers' Club of that city, and had a wide acquaintance. When he was transferred to Knoxville, Tenn., he became associated with the Technical Society, which includes in its membership representatives of all branches of the engineering profession.

Although Mr. Tyrrell was eminent in his chosen field, he himself felt that his outstanding achievement was in directing men. He was justly proud that he was able to perform effectively the duties of management as differentiated from an impersonal practice of engineering. He handled the personnel under him successfully, and organized his men into an efficient working unit. He knew that knowledge and practice of civil engineering are prime requisites for an engineering career, but he felt that the basis of larger success was in personality and in qualities of leadership. He strove earnestly to attain this end.

---

[1] Memoir prepared by J. B. Akers, M. Am. Soc. C. E.

Mr. Tyrrell took pride and found satisfaction in furthering the careers of young engineering school graduates who were employed by the Southern Railway Company. Many young engineers were trained and guided in their formative years by Mr. Tyrrell.

Mr. Tyrrell was a lovable man, and had a great many friends. He was kindly, unpretentious, and richly deserved the confidence placed in him by all who knew him.

Mr. Tyrrell did not find much time for sports, although he was very much interested in them. In his later years he was a member of the Holston Hills Golf and Country Club at Knoxville, where he tried earnestly to develop a good game of golf. Only a few days before his death he said that he had about "lost hope," and that he still could not shoot better than one hundred —he even admitted to occasionally missing the ball. For many years he and his family made an annual pilgrimage to the New Jersey seacoast to fish, and, at the same time, to spend a happy period with his parents. He was an active member of the American Railway Engineering Association.

On April 10, 1907, Mr. Tyrrell was married to Amanda M. Haines in Washington, D. C. He is survived by his widow; his two sons, Harry E., Jr., and Maxwell H. Tyrrell; his mother; his father; and a sister, Mrs. Elsie Tyrrell Hebrew.

Mr. Tyrrell was elected a Member of the American Society of Civil Engineers on May 28, 1923.

THOMAS UTEGAARD, M. Am. Soc. C. E.[1]

DIED DECEMBER 17, 1943

Thomas Utegaard was born in Eau Claire, Wis., on December 9, 1893, the son of Ole T. and Ragna (Brekken) Utegaard. After being graduated from high school, he entered the College of Engineering of the University of Wisconsin at Madison. In 1917 after his graduation from the University with the degree of Bachelor of Science in Civil Engineering, he worked for a while for the Dravo Construction Company, Pittsburgh, Pa. In January, 1918, he enlisted in the U. S. Army as a private at Columbus, Ohio. Later he entered officer's training school at Camp Grant, Ill., and was commissioned a Second Lieutenant. He served for nine months in France with the 56th Coast Artillery Regiment.

After being discharged from the Army early in 1919, Thomas Utegaard worked for a time for the St. Joseph Stockyards Company, South St. Joseph, Mo., later that year entering the employ of the City of Janesville, Wis., in the City Engineer's department. On September 1, 1920, he was employed by the Consolidated Water Power and Paper Company, and moved to Wisconsin Rapids, Wis. He remained with this company until early in 1943, when he was commissioned a Lieutenant Commander in the Navy.

---

[1] Memoir prepared by Carl A. Cajanus, M. Am. Soc. C. E.

Between 1920 and 1926, Thomas Utegaard worked as draftsman, structural designer, instrumentman, and chief of party. The Consolidated Water Power and Paper Company was, at that time, laying the groundwork for a 20-yr program of expansion. Thomas Utegaard conducted the early surveys and investigations for the conservation of water resources and the development of power on the Wisconsin River and its tributaries, between Stevens Point and Mosinee and Petenwell and Germantown in Wisconsin. During this period he also drew the plans for a large warehouse at the Wisconsin Rapids mill of the Consolidated Water Power and Paper Company.

Between 1926 and 1943, Thomas Utegaard was assistant chief engineer of Consolidated Water Power and Paper Company, handling all the civil engineering work of the company. His first important assignment was the construction of a complete mill (a sulphite pulp mill, a two-machine paper mill, and a steam power plant) for the production of newsprint at Port Arthur, Ont., Canada.

In addition to the main plant at Wisconsin Rapids and the newly constructed mill at Port Arthur, the Consolidated Water Power and Paper Company operated plants in Wisconsin at Biron, Stevens Point, and Appleton. Because raw materials had become scarce in Wisconsin, the production of newsprint was gradually discontinued and this product was manufactured more and more in Canada, where the wood supply was still plentiful. This trend made it necessary for the Consolidated Water Power and Paper Company to discontinue the production of newsprint and to convert its facilities to the production of other kinds of paper. The transition from the manufacture of newsprint to better grades of paper required a great deal of equipment and additional buildings. During this period, Thomas Utegaard supervised the design and construction work at all the plants of the Consolidated Water Power and Paper Company.

At the Wisconsin Rapids plant, additions to the digester building of the sulphite pulp mill were built in 1926 and 1937. Because the company was making a high-grade white paper, a filter plant for the filtration of water was needed and was erected in 1927 with additions in 1929 and 1937. The steam power plant was somewhat antiquated and an entirely new boiler house and steam turbine plant were built in 1927 with additions in 1938 and 1941. The quality of the paper required not only clean water, but also the bleaching of pulp for which a plant was built in 1929 and an addition in 1937. The manufacture of paper required much more floor space than had been needed previously and additions for the handling, finishing, and loading of the paper were built in 1929, 1937, and 1941. In 1929, an eighteen-car garage was provided for the storing of cars and trucks. In 1937 a very large expansion program was completed, consisting of a building for a new large paper machine of the latest design, which considerably increased the output of the mill. In the same year a large four-story addition was necessary to house the mill offices.

The factors which influenced the changes at the Wisconsin Rapids plant also affected the production at the other plants of the company. Between 1929 and 1936, Thomas Utegaard designed and supervised the construction of certain additions at the Biron mill of the company, consisting of a water filtration plant, a department for the cleaning and preparing of the pulpwood, and a building for the sorting, packing, and shipping of the finished paper. Between 1928 and 1931, the sulphite pulp mill at Appleton was entirely rebuilt under his direction. At the Stevens Point plant, a storage building was added in 1935.

Thomas Utegaard also designed and supervised construction of a paper box plant in 1930 and a paper carton plant in 1939 for the Ahdawagam Paper Products Company, a subsidiary of the Consolidated Water Power and Paper Company. A short time before he left to assume his duties with the U. S. Navy, he designed and began construction on a plastics press building.

Two of the power dams owned by the Consolidated Water Power and Paper Company, at Wisconsin Rapids and at Biron, were of wood-crib construction. In 1936 the Biron dam had to be replaced by a new concrete dam. The dam at Wisconsin Rapids was replaced with a concrete dam in 1941. Thomas Utegaard designed and supervised the construction of both of these structures.

A project, for which Thomas Utegaard made preliminary surveys in the early 1920's, was the Big Eau Plaine reservoir, completed in 1936. It consisted of damming up the Big Eau Plaine River (a tributary of the Wisconsin River) with an earth dam more than a mile long. Another project for which the preliminary work was done in the 1920's was the Du Bay power project, consisting of a power house with generating equipment of 9,000 kva, under a 25-ft head and an earth dam one-and-three-quarters miles long. This was completed under the direction of Thomas Utegaard in 1942 and early 1943. In 1942 he designed the structural framework and supervised the construction of a hospital in Wisconsin Rapids for Childs and Smith, architects of Chicago, Ill.

In 1933, at the request of state authorities, Thomas Utegaard was given a leave of absence from the Consolidated Water Power and Paper Company for about three months to enable him to assume the position of Regional Director of the Civil Works Administration.

Thomas Utegaard was respected in the community where he had lived for almost twenty-three years. His ability as an engineer was recognized by his employer, as is shown by the following statement of Stanton W. Mead, vice-president of the Consolidated Water Power and Paper Company:

> "Tom Utegaard's service of 23 years to Consolidated was of a kind that is impossible to replace. His interests and the responsibilities which he always took eagerly included engineering tasks of every size and scope. Every one of these tasks undertaken by him or his department was done thoroughly and well. In each instance he planned for the future stability and performance. Work and service were an enjoyment for Tom Utegaard. Those who worked with him soon sensed his enjoyment in work well done and readily followed his leadership.

"Buildings which Tom Utegaard engineered and supervised while under construction are prominent in our mills and in the community and are monuments to his fine ability."

The following editorial was published in *Wisconsin Rapids Daily Tribune* on December 23, 1943:

> "On Wednesday the comrades and friends of Lieutenant Commander Tom Utegaard gathered for a final tribute to a man who twice offered his services to his country in world-wide conflicts. That distinction was not the only one Tom Utegaard possessed, although it is one he bore with real honor.
>
> "Tom Utegaard was a builder, a constructor of things which will endure because he planned them well and demanded the best of materials and workmanship.
>
> "He knew that no edifice would long stand that was not founded upon solid foundations, erected with strong and lasting materials and fabricated with careful craftsmanship. The many buildings he engineered for the Consolidated, the installations such as the Du Bay and Wisconsin Rapids dams, will outlive all of us now on this earth. They are truly fine monuments to a man with a capable mind and an honest spirit.
>
> "As we review his contribution in a material way, we have explored his character too. The solid physical edifices were only a symbol of his character. He knew his philosophy too, and it was based on the same forthright reasoning that the only enduring human relationship was built of the same qualities.
>
> "There was only one route so far as Tom Utegaard was concerned—the right way—and it was the straight line between two points both honestly conceived. Two and two in human relationships didn't add up to either three or five with him. There was only one answer, the same answer that he got on his drawing board and work sheets.
>
> "On the drawing board of life, as well as in the blueprint laboratory, two and two made four, not as a matter of expediency but because there could be no compromise with its validity. That was the rule on which Tom Utegaard based his life."

Thomas Utegaard died on December 17, 1943, at the Navy Hospital in Brooklyn, N. Y., where he had been a patient since May, 1943. After his training at Norfolk, Va., he had been assigned as Public Works Officer of the U. S. Naval Supply Depot, at Bayonne, N. J.

He was a member of the American Concrete Institute, and of the American Legion, the Elks Lodge, and the Bull's Eye Country Club at Wisconsin Rapids.

On May 31, 1918, Thomas Utegaard was married to Isabel E. Fletcher at Columbia, S. C., just before sailing overseas. Besides his widow, he leaves three sons, Thomas F., John H., and Rolf; and four brothers, Olin, Arthur, Olaf, and Harold.

Thomas Utegaard was elected a Member of the American Society of Civil Engineers on July 13, 1942.

JEPTHA ALAN WADE, M. Am. Soc. C. E.[1]

DIED JULY 4, 1944

Jeptha Alan Wade, the son of George Henry Wade and Matilda S. (Clements) Wade, was born in Eaton County, Michigan, on February 8, 1887.

Jeptha Wade attended local schools in Eaton County and was graduated from high school at Charlotte, Mich. He then attended Olivet College at Olivet, Mich., and was graduated *summa cum laude* in 1908 with the degree of Bachelor of Arts. From 1908 until 1911, he was a high school teacher and principal of schools at St. Johns and Monroe, Mich., and at Reno, Nev. He entered the University of Michigan at Ann Arbor in 1911 and was graduated in 1913 with the degree of Bachelor of Civil Engineering.

For the first fourteen years of his professional practice he served in various positions which gave him a thorough background for his later work:

July, 1913, to July, 1916—draftsman for S. Morgan Smith Company, manufacturers of hydraulic turbines.

July, 1916, to December, 1916—draftsman with George F. Hardy, M. Am. Soc. C. E., on design of paper mills, etc.

January to July, 1917, and December, 1917, to February, 1918—engineer with British Chemical Company of Trenton, Ont., Canada, first on field and office work in charge of design and construction of water and sewer systems for a trinitrotoluene (TNT) plant; and during the last two months as assistant chief engineer in charge of new construction.

September to December, 1917—superintendent of construction on steam power plant for Esselstyn and Murphy of Detroit, Mich.

February to September, 1918—hydraulic designing engineer for Graham, Anderson, Probst and White of Chicago, Ill., in charge of design of a large pumping station at the United States Explosive Plant at Nitro, W. Va.

September to December, 1918—assistant to area supervisor in nitrating area, plant C at Nitro, in responsible charge of construction work.

January to July, 1919—engineer on valuation work for Henry Earle Riggs, Past-President and Hon. M. Am. Soc. C. E., in Ann Arbor, in charge of unit price investigations, editing reports, etc.

July to December, 1919—field engineer, Realty Construction Company of Flint, Mich., in charge of engineering on the construction of large hotel and bank buildings.

December, 1919, to February, 1920—special assistant, Technical Section, War Department Claims Board, reviewing and reporting on claims in connection with canceled war contracts.

February to October, 1920—assistant to engineer in charge of hydraulic structures, J. G. White Engineering Corporation, making and checking calculations for stability of dams and powerhouses; designing powerhouses, penstocks, head gates, hoists, canals, etc.; and making computations for available power, storage, required flywheel for speed regulation, etc.

---

[1] Memoir prepared by Howard A. Harris, Jr., Assoc. M. Am. Soc. C. E.

October, 1920, to February, 1921—hydraulic engineering assistant to chief engineer, Guggenheim Brothers of New York, N. Y., in charge of design of hydraulic plants and of investigations and reports on hydraulic problems.

February, 1921, to July, 1923—engineer with James H. Fuertes,[2] M. Am. Soc. C. E., consulting engineer of New York City in charge of design and construction of municipal pumping station and of pipe lines at Harrisburg, Pa.

July, 1923, to October, 1924—engineer with Viele, Blackwell and Buck on power plant design.

February, 1925, to July, 1927—designer with Nicholas S. Hill, Jr.,[3] M. Am. Soc. C. E., on various municipal water and sewer projects.

From July, 1927, to March, 1933, Jeptha Wade was associated with the Federal Water Service Company as assistant chief engineer. During this period he supervised the design and construction of water softening plants at Massillon and Marysville, Ohio. In April, 1933, he went to California as chief engineer of the California Water Service Company. In this position he was responsible for the design and construction of all types of water works facilities on twenty operating properties—numerous wells and pumping stations, three water treatment plants, a 10-mgd water supply for industrial plants, and many miles of transmission and distribution mains. Mr. Wade was author of numerous unpublished technical reports on water resources, plans for developing and enlarging existing plants, and papers presented before the California section of the American Water Works Association.

On July 9, 1918, Jeptha Wade was married to Jessie Ada Baker in Flint. He is survived by his widow and two children, Jeptha A. Wade, Jr., and Margaret Ann Wade.

A man of high character, Mr. Wade was very thorough in his work. He was respected both by those who employed him and by his fellow workers. He was extremely sincere and honest in all his work and dealings. His professional ethics were the highest and he followed his beliefs in all his actions. He was a genial companion and a cooperative associate and was held in highest regard by all who knew him. Interested in his fellow men, particularly in those young engineers who worked under him, he gave much helpful assistance both professional and personal.

He was a member of Sinfonia, Tau Beta Pi, and Sigma Xi engineering societies; the Engineers Club of San Francisco, Calif.; the Peninsula Water Works Association; and the American Water Works Association (director of the California section for two years). He was a member of Maple Masonic Lodge, Maplewood, N. J., and a member of the Congregational Church.

Mr. Wade was elected an Associate Member of the American Society of Civil Engineers on November 27, 1917, and a Member on October 15, 1923.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 96 (1932), p. 1482.

JOSEPH PALMER WADHAMS, M. Am. Soc. C. E.[1]

DIED JANUARY 17, 1944

Joseph Palmer Wadhams was born in Goshen, Conn., on April 22, 1877, the son of Francis M. and Frances (Palmer) Wadhams.

The family later moved to New Haven, Conn., and, after completing the college preparatory studies at Hillhouse High School, Joseph Wadhams entered the Sheffield Scientific School of Yale University in New Haven, from which he was graduated in 1899 with the degree of Bachelor of Philosophy.

In 1900 Mr. Wadhams established a private practice as consulting engineer in Torrington, Conn. At this time he was also engineer for the Torrington-Winchester Street Railway Company. In 1905 he entered the employ of the New York, New Haven and Hartford Railroad Company, and was engaged in the electrification of the New York Division from Woodlawn, N. Y., to New Haven, and of the Harlem River Branch from New Rochelle, N. Y., to the Harlem River. He later moved to Boston, Mass., where he was in charge of the office, preparing the electric traction plans for the electrification of the Boston Terminal and the Roxbury-Dedham branches of the Boston and Providence Railroad Corporation.

From 1912 to 1915 Mr. Wadhams was engineer in charge of the firm of McHenry and Murray in New Haven. During 1915–1916 he served as street commissioner and city engineer of Norwalk, Conn.

In 1919 Mr. Wadhams was appointed engineer for the Public Utilities Commission of the State of Connecticut, in which position he ably served until his death. He was the commission's chief expert on evaluation of water companies and an authority on rates. He represented the National Society of Public Utilities Engineers at various meetings in Washington, D. C.

Mr. Wadhams was long a member of Plymouth Congregational Church of New Haven, being on the board of deacons and president of the finance committee. He belonged to the Graduate Club of New Haven, University Club of Hartford, Conn., the Torrington Country Club, and the Masonic fraternity of Torrington. A member of the Connecticut Society of Civil Engineers, Mr. Wadhams was elected president in 1926, became a life member in 1938, and was chosen an honorary member in 1942. A former President of the Connecticut Section of the Society, for a period of years, he served as Secretary and Treasurer of the Section.

In 1902 he was married to Ethel Hubbell Clarke of New Haven. He is survived by his widow; a daughter, Dorothy Palmer Wadhams (Mrs. Stuart Cleaveland); and a granddaughter, Dorothy Wadhams Cleaveland.

During his entire career, Mr. Wadhams practiced engineering. A man of sterling character and high ideals, he was quiet and reserved. He was greatly admired by all with whom he came in contact, both socially and professionally, for his honesty, loyalty, perseverance, and for his charming and genial good nature.

---

[1] Memoir prepared by Clarence M. Blair, M. Am. Soc. C. E. Mr. Blair died on May 21, 1944.

Mr. Wadhams was elected an Associate Member of the American Society of Civil Engineers on October 31, 1911, and a Member on June 24, 1914.

ELTON DAVID WALKER, M. Am. Soc. C. E.[1]

Died February 24, 1944

Elton David Walker was born on March 8, 1869, in Taunton, Mass., the son of Benjamin D. and Ruth (Cobb) Walker. He received his education in the public schools of Taunton and at the Massachusetts Institute of Technology in Boston from which he was graduated with the degree of Bachelor of Science in Civil Engineering in 1890. After one year as assistant in civil engineering at his alma mater, he gained practical experience in several types of engineering work before finally returning to the teaching profession. During the latter half of 1891 he was civil engineer in charge of construction with the Constructing Quartermaster at Fort Sheridan, Ill. For the next three years he was a member of the engineering firm of Walker and Gallagher of Chicago, Ill. From 1894 to 1900 he taught civil engineering at Union College in Schenectady, N. Y.—the first three years as instructor and the last three as assistant professor. During his last two years at Union he was also resident hydrographer for the U. S. Geological Survey.

In October, 1900, Professor Walker went to The Pennsylvania State College at State College where he taught until he retired in July, 1939. Successively, he held the rank of Assistant Professor of Civil Engineering, Professor of Hydraulic and Sanitary Engineering, and, during the last thirty-three years, Head of the Department of Civil Engineering. From 1913 to 1915 he was also acting Dean of the School of Engineering.

From 1917 to 1919 Professor Walker served in France as Captain with the 15th Engineers, U. S. Army, engaged on construction work—railroads, water supply and drainage systems, warehouses, hospitals, barracks, and preliminary studies of harbor projects. He was awarded the Order of the Purple Heart, and a citation by Gen. John J. Pershing "for exceptionally meritorious and conspicuous services with the 15th Railway Engineers at Jonchery and Liffol-le-Grand." After the war he continued in the Army Reserve Corps and became a Colonel of Engineers, participating actively in the Corps until 1942. He was president of the Centre County Chapter of the Reserve Officers Association of the United States, and later first vice-president of the Pennsylvania department of that organization.

Professor Walker had a consulting engineering practice from 1892 until about two years before his death. He designed and directed construction of sewage treatment plants and sewer and water supply systems, and did valuation work. He served as expert witness in water works cases; and, as special engineer for the Pennsylvania State Department of Health, investigated and reported on cases of alleged water pollution, on applications for permits to construct water works and sewage systems, and on requests for water company charters.

---

[1] Memoir prepared by L. S. Rhodes, Associate Prof. of Civ. Eng., The Pennsylvania State College, State College, Pa.

While teaching at Penn State, Professor Walker supervised the operation of the college sewage treatment plant for a time, and later acted in an advisory capacity. At this treatment plant he conducted research on open versus closed trickling filters, liquid chlorine versus bleaching powder as a disinfectant for sewage plant effluents, and treatment of creamery wastes.

In addition to the Society, Professor Walker belonged to the following technical organizations: The New England Water Works Association, the Society for the Promotion of Engineering Education, the American Association of University Professors, and the Society of American Military Engineers. He was a fellow of the American Public Health Association. In 1926 he called a conference at State College from which developed the Pennsylvania Water Works Operators' Association and the Pennsylvania Sewage Works Association. These two organizations were originally one association of which Professor Walker was the first president. He was also a director of the Engineers' Society of Pennsylvania.

A director of the University Club of State College, Professor Walker was its president from 1912 to 1915, during which time the present clubhouse was built. He was active in St. Andrews Episcopal Church of State College, being for a long time a member of the vestry and taking an important part in the construction of the present church edifice. He was a member of Sigma Xi, Phi Kappa Phi, Tau Beta Pi, Chi Epsilon, and Scabbard and Blade honor societies; and of Delta Kappa Epsilon, a social fraternity.

While at Union College, in 1896 Professor Walker was married to M. Louise Brownell of Schenectady. Two children, Dudley Brownell and Robert Brownell, were born to them. Dudley died in February, 1907, and Robert in April, 1912. Both Mr. and Mrs. Walker came from early New England families. He is survived by his widow and by a brother, Chester E.

As a citizen, as an engineer, and as a teacher, Professor Walker had the highest ideals, character, and integrity. His life exemplified these qualities. The exactness of his memory was always a source of amazement to his friends.

Professor Walker was elected a Junior of the American Society of Civil Engineers on October 4, 1892; an Associate Member on June 1, 1898; and a Member on September 5, 1900.

JOSEPH WEIDEL, M. Am. Soc. C. E.[1]

DIED JANUARY 6, 1945

Joseph Weidel was born on February 22, 1873, on a farm near Lagrange, Fayette County, Tex. He was the son of Joseph Weidel and Elisabeth (Seibert) Weidel. His father and mother and older sister, Marie, came to Texas from Germany in 1871. His mother died when he was seven years old.

Mr. Weidel obtained his early primary education in the public schools at Kinkler, a small community about seven miles north of Hallettsville, Tex. At the age of thirteen he left the farm, learned city ways at Houston and Galveston, Tex., and within two years decided to become an engineer. He studied intensively at night school in San Antonio, Tex., and entered the Agricultural and Mechanical College of Texas at College Station, in the fall of 1889. He was graduated from the College of Civil Engineering at that institution in 1893, with the degree of Bachelor of Civil Engineering.

His engineering career began in 1895 as draftsman for M. Guggenheim's Sons at Monterrey, Mexico, assisting on the plans for a refinery being planned for construction at Perth Amboy, N. J. In a short time he was transferred to New Jersey and worked on the design and plans for a variety of furnaces; machinery, gas-producing, and distributing facilities; electrolytic plant; and structural steel buildings. The plant was placed in operation in 1896.

During the winter of 1896–1897, he taught mathematics and drafting in a private school in Chicago, Ill. He then returned to Texas because of poor health.

Late in 1899 he joined the Buck Exploration Company as a surveyor and draftsman on a prospecting expedition across Mexico from the Rio Grande to the State of Sinaloa. In October, 1900, he entered railroad engineering as chainman for The Atchison, Topeka and Santa Fe Railway Company at Pueblo, Colo. In 1901 he was promoted to transitman, in charge of second-track construction between Morley and Wootton in southern Colorado. In 1902 he acted as building inspector on the company's new shops and terminal being constructed at Topeka, Kans., where he conducted an investigation of systems of heating for large plants such as the railroad shops.

In September, 1902, Mr. Weidel returned to Mexico as division engineer on construction for the Mexican Central Railroad Company on the line from San Pedro to Paredon in the State of Coahuila. In 1903 he became field engineer in charge of a party on railroad location for the railroad company in the State of Veracruz. On March 1, 1904, he returned to The Atchison, Topeka and Santa Fe Railway Company as assistant engineer on the construction of new shops and terminals at La Junta, Colo. In January, 1905, he directed construction on the Shoemaker to Watrous change of line in northern New Mexico, and in May he was transferred to the Canadian to

---

[1] Memoir prepared by G. W. Harris, M. Am. Soc. C. E., J. DeN. Macomb, Assoc. M. Am. Soc. C. E., and F. B. Baldwin, who succeeded Joseph Weidel as Valuation Engr. System, The Atchison, Topeka and Santa Fe Ry. Co., Chicago, Ill.

Glazier change of line in the Texas panhandle. In 1906 he was in charge of construction of the Holly and Swink Railway in eastern Colorado.

During 1907 and 1908 Mr. Weidel supervised the construction of a new tunnel for The Atchison, Topeka and Santa Fe Railway Company at Raton Pass, just south of the Colorado-New Mexico boundary. From 1908 to 1912 he was engaged in the standardization of plans for track, bridges, and buildings. From 1912 to 1914, he was in charge of constructing the line from Lubbock, Tex., to Texico, N. Mex. In 1915 he was appointed valuation engineer, System. He retired on January 15, 1943.

Eminently qualified by education and experience as an engineer to locate and build railroads, Mr. Weidel also had that tenacity of purpose and mental training which enabled him to analyze and unfold the great mass of details and facts involved in the stupendous task of inventorying, classifying, and evaluating the physical properties of a large railway system. He was well known by his associates for his ability on construction, but of greater importance was his contribution to the valuation field. As a valuation engineer, he was known and highly regarded throughout the United States.

A familiarity with the German language gained early in life and a knowledge of Spanish acquired later not only gave him an entree to literature, but also equipped him as a translator. He was a member of the American Railway Engineering Association and for many years a member of the Western Society of Engineers.

In 1909 Mr. Weidel was married to May Genevieve Baston of Hamilton, Ont., Canada. He is survived by his widow; a son, Joseph Charles; and two daughters, Wilhelmina Elisabeth (Mrs. Verne J. McCaul) and Marie Josephine (Mrs. Wesley A. Hodgetts).

Mr. Weidel was elected an Associate Member of the American Society of Civil Engineers on July 10, 1907, and a Member on November 26, 1918. He became a Life Member in January, 1942.

WILLIAM HENRY WETZLER, M. Am. Soc. C. E.[1]

DIED DECEMBER 23, 1944

William Henry Wetzler, the son of Joseph and Crescenz (Ruf) Wetzler, was born at Monroe, Wis., on March 13, 1880. Later, his parents moved to Beloit, Wis., where he spent his boyhood and youth in grade school and high school. He entered the University of Wisconsin at Madison in the fall of 1902 and was graduated in 1906. He was a self-supporting student—earning his way through the university and at the same time studying the very difficult civil engineering course.

Mr. Wetzler's early experience, like that of most young engineers, was diversified both as to type and location. However, most of his professional career was devoted to the design of hydraulic structures of all kinds, at which he was a recognized expert.

---

[1] Memoir prepared by L. F. Harza, M. Am. Soc. C. E.

Immediately after graduation, he entered the employ of Daniel W. Mead, Hon. M. and Past-President, Am. Soc. C. E., where he remained for one year. Then, after taking a competitive examination, he was appointed an assistant engineer with the Board of Water Supply of New York City (N. Y.). He spent two and one-half years on design and construction in connection with the Olive Bridge Dam and Ashokan Reservoir and on the design for a sanitary trunk sewer in the Esopus watershed. He then served the Arnold Company of Chicago, Ill., on the design of irrigation and hydroelectric structures for two and one-half years. From 1912 to 1915 he was in direct charge of hydroelectric structures for the H. M. Byllesby Company of Chicago. For the next two years he supervised the design of a hydroelectric project for James O. Heyworth,[2] M. Am. Soc. C. E., in Canada.

Like most engineers, during World War I, Mr. Wetzler left his usual activities for war work and devoted his time to the design of ships for the Emergency Fleet Corporation at Washington, D. C. He was also a surveyor of ships for the American Bureau of Shipping in New York City.

After the war, he returned to his chosen field of hydraulic design, and was with the L. E. Myers Company of Chicago, on the design of hydroelectric plants for two years. He then served as chief draftsman for the Sinclair Refining Company of Chicago for two years on refinery design—another departure from his chosen work. Evidently he did not like oil as well as water and, in 1924, returned to the design of hydraulic structures—this time for the Harza Engineering Company of Chicago. From 1925 to 1929 he was in California, being employed first by the Department of Water and Power of Los Angeles on the Colorado River Aqueduct and then by the Los Angeles County Flood Control District on the design of gravity and multiple arch dams. From 1929 to 1942 he was employed by the Bureau of Water of the City of Chicago, in charge of a section of the designing division. On November 30, 1942, he moved to Southern California—the place he loved most.

Mr. Wetzler was always a thorough student of the problems before him; a tireless and efficient worker, who sought perfection as far as humanly possible in design and execution. He loved his work, took it seriously, and never neglected any detail which might help to improve the final product. To all executives, a most difficult problem is to find men who can be assigned a job without further worry, supervision, checking, conferences, and frequent revisions. From long experience as a colleague or employer, the writer can state that Mr. Wetzler was one of the few engineers to whom a difficult problem could be assigned with complete confidence. Mr. Wetzler was one of those men to whom engineering was not merely a means of livelihood. He put his very best energy, talent, and perseverance into the job—in fact, his work was his life and his one great supreme interest next to his wife. He belonged to the Society of Naval Architects and Marine Engineers.

---

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 93 (1929), p. 1826.

On June 1, 1907, in Buffalo, N. Y., he was married to Mary Crook. He is survived by his widow.

Mr. Wetzler was elected a Member of the American Society of Civil Engineers on April 14, 1919.

LINDSEY WOOD WHITEHEAD, M. Am. Soc. C. E.[1]

DIED JULY 15, 1944

Lindsey Wood Whitehead, the son of Bower T. and Harriet (Wood) Whitehead, was born on June 16, 1888, in Brookings, S. Dak. He received his early education in the Brookings public schools. In 1908 he was graduated from South Dakota State College of Agriculture and Mechanical Arts at Brookings, with the degree of Bachelor of Science in Mathematics. For the next two years he served his alma mater as an assistant in mathematics.

From June, 1911, to August, 1912, he was rodman and instrumentman for the Grand Trunk Pacific Railroad Company, engaged on construction of bridges and trestles and on inspection of cement and concrete. In September, 1912, he entered the Massachusetts Institute of Technology at Boston, receiving the degree of Bachelor of Science in Civil Engineering in 1913. In 1914 he was assistant in civil engineering at the Massachusetts Institute of Technology. In June, 1914, Mr. Whitehead again left the teaching field to become instrumentman and inspector for E. Worthington, a consulting engineer of Dedham, Mass. In this capacity, he worked on general municipal engineering, surveying, and highway construction.

Mr. Whitehead returned to teaching in September, 1916, when he was appointed instructor in civil engineering at The Pennsylvania State College in State College. Later he became associate professor of civil engineering in charge of the division of surveying, which position he held until his death. Professor Whitehead was largely responsible for the design and construction of the college's surveying-instruction summer camp, which has permanent buildings with water supply, sewage disposal, and electric lighting. This camp was his pet hobby. During his vacations and his spare time he worked for the Department of Grounds and Buildings of the college on extensions to the sewer system, prepared plans for the growth of the campus, and made an accurate survey of campus buildings, streets, and of water, sewer, electric, and steam lines. He also served in 1931 as assistant borough engineer for the Borough of State College, in charge of plans, specifications, and construction of a storm sewer.

In addition to the Society, Professor Whitehead was a member of Chi Epsilon (honorary civil engineering fraternity), the Society for the Promotion of Engineering Education, and the American Association of University Professors.

---

[1] Memoir prepared by L. S. Rhodes, Associate Prof. of Civ. Eng., The Pennsylvania State College, State College, Pa.

In 1913, while at the Massachusetts Institute of Technology, Professor Whitehead was married to Marie Laut of Bremen, Germany. He is survived by his mother; his widow; four daughters, Grace (Mrs. F. G. Koch), Lyndall (Mrs. J. C. Wert), Esther (Mrs. L. H. Casper), and Louise (Mrs. J. K. Poorman); and one son, Bower T. Whitehead (in the United States Army).

Larry, as Mr. Whitehead was known to all his associates, lived in Boalsburg, Pa. (near State College), where he was a member of the Independent Order of Odd Fellows. He was most active in the Pennsylvania State College Student Chapter of the Society, serving as faculty adviser and assisting at all meetings. His dealings with students and associates were always characterized by great fairness and justice, and he held the respect and affection of all who worked with him.

Professor Whitehead was elected a Member of the American Society of Civil Engineers on August 12, 1935.

JULIUS EDGAR WILLOUGHBY, M. Am. Soc. C. E.[1]

DIED MARCH 11, 1944

Julius Edgar Willoughby was born on October 12, 1871, in Arkadelphia, Ala. He was the son of John Paul and Mary Jane (Cosby) Willoughby and the grandson of John Hincky and Amanda (Tyler) Willoughby. The Willoughbys were descended from a long line of distinguished English ancestors and the Tylers belonged to a Virginia family well known in state and national affairs.

John Paul Willoughby was schoolmaster at Arkadelphia, and later a merchant at Blount Springs, Ala. However, business life was not congenial and he gave up that pursuit to enter the service of the Louisville and Nashville Railroad Company as land agent. After various promotions he was appointed general land agent and geologist for the State of Alabama, which position he held at the time of his death in 1910. Julius Willoughby's grandfather, John Hincky Willoughby, was a physician and Presbyterian minister —ministering to both the physical and spiritual welfare of man.

Descended on both sides from professional forebears, it was natural for Mr. Willoughby to seek a college education. He was graduated from the University of Alabama at University in 1892 with the degree of Bachelor of Civil Engineering. Later he received the degree of Civil Engineer from the same institution. In recognition of his scholarship, he was senior speaker at the commencement exercises—the highest honor conferred at that time. Since it was a state-supported institution, the University of Alabama included military training as part of the curriculum. When he was graduated, Mr. Willoughby was Captain of Company D, and was listed in the Army register as a desirable officer for the U. S. Army. He was a member of the Kappa Alpha fraternity.

---

[1] Memoir prepared by George H. Maurice, M. Am. Soc. C. E.

Immediately after graduation Mr. Willoughby entered the employ of the Louisville and Nashville Railroad Company and thus began his career in railroad engineering. His first assignment was in the Land Office Department, followed in May, 1900, by his appointment as assistant chief engineer on the construction of new lines in Alabama. In April, 1901, he was promoted to engineer of construction for the Alabama, Florida and Gulf Railroad Company on about twenty-five miles of road, including a drawbridge. From March to September, 1902, he served as division engineer on location and construction; and from September, 1902, to January, 1905, as chief engineer for the Knoxville, La Follette and Jellico Railroad Company on about 105 miles of track with eight tunnels 300 ft to 3,600 ft long. He also supervised the building of terminals in Knoxville, Tenn. From January, 1905, to March, 1912, he was engineer of construction for the Louisville and Nashville Railroad Company on the reconstruction of 110 miles of track for the Atlanta, Knoxville and Northern Railway Company and other divisions. He was also engineer of construction on 88 miles of track for the Cambria Southern Railway Company and the Cartersville Branch of the Atlanta, Knoxville and Northern Railway Company (32 miles of double track from Corbin to Livingston, Ky., the West End Freight Yards in Atlanta, Ga., and many branch lines and spurs). Also, during this period, he was chief engineer of the Cairo and Thebes Railroad Company. In April, 1912, he was appointed chief engineer of the Caribbean Construction Company and of the National Railroad of Haiti.

Mr. Willoughby returned to the United States in June, 1913, as assistant engineer for the Atlantic Coast Line Railroad Company, being promoted to chief engineer in September, 1915. He retired on January 1, 1942, and became a consulting engineer. He was also chief engineer of certain subsidiaries and some affiliated lines. During this time, the double track of the Atlantic Coast Line Railroad Company was built, and the entire roadway and track were strengthened.

In 1895, at Blount Springs, he was married to Mary A. Byars, who, with two daughters, Mary and Ruth, survives him. An only son, William, died in 1936. From the time of his connection with the Atlantic Coast Line Railroad Company until his retirement, Mr. Willoughby resided in Wilmington, N. C. He then returned to his home town, Blount Springs. In 1942 he moved to Sarasota, Fla., where he died on March 11, 1944.

Mr. Willoughby took an active part in the North Carolina Section of the Society, serving on numerous committees and as President in 1928–1929. He was also a member of the North Carolina Society of Engineers, American Railway Engineering Association, Society of American Military Engineers, American Association for the Advancement of Science, and North Carolina Academy of Science. He was the author of a paper[2] and numerous discussions in the Society's publications.[3,4]

---

[2] "Reconstructing the Sandbar Ferry Bridge," by J. E. Willoughby, *Civil Engineering*, October, 1932, p. 633.

[3] *Transactions*, Am. Soc. C. E., Vol. LXXII (June, 1911), p. 193; Vol. LXXXV (1922), p. 999; Vol. 91 (1927), p. 733; Vol. 96 (1932), p. 898; Vol. 99 (1934), p. 36 and p. 895; Vol. 102 (1937), p. 785; and Vol. 103 (1938), p. 1310 and p. 1561.

[4] *Civil Engineering*, February, 1932, p. 109; and March, 1936, p. 205.

A mere recital of a man's professional accomplishments, although interesting to his fellow engineers as a gage of ability, is not sufficient to evaluate his worth to his fellow men. From personal contacts and many letters received from his warmest friends and associates, the character of Mr. Willoughby shines out. The person who probably knew him best paid tribute to his quiet, unassuming, genial, and happy disposition. He was devoted to his family, loyal to his friends, and generous to a fault, giving freely to every worthy cause. Other friends, especially J. Houstoun Johnston, M. Am. Soc. C. E., praised Mr. Willoughby's zeal and energy, coupled with an unflagging loyalty to duty. He met all issues squarely and never shirked responsibility. As an example of this quality, when the Black Oak Ridge tunnel in eastern Tennessee on the Knoxville, La Follette and Jellico Railroad was constructed, at great personal risk he inspected every foot of the bore, through treacherous and extremely dangerous strata where slips and falls constantly occurred. There is a legend, probably founded on fact, that, after he was made assistant chief engineer of the Atlantic Coast Line Railroad Company, he walked over and inspected every mile of the system—about 4,500 miles. His work was his hobby, although he found recreation in reading and in national sports. He was a fine and genial host, with an interesting sense of humor. He was a staunch member of the Methodist Church for fifty years, and served for a great part of that time as steward. With his concise and penetrating mind, Mr. Willoughby saw issues clearly and made sound judgments. He was liberal in his donations to church buildings, college debts, college scholarships, orphanages, and the poor. In truth, it may well be stated, "The world is better for his having passed this way."

Mr. Willoughby was elected a Member of the American Society of Civil Engineers on June 1, 1909. He became a Life Member in January, 1942.

DONALD WITTEN, M. Am. Soc. C. E.[1]

DIED OCTOBER 4, 1944

Donald Witten, the son of Thomas A. and Carrie (Bailey) Witten, was born in Kansas City, Mo., on February 20, 1890. He was of English descent, both his maternal and paternal ancestors having settled in America many years prior to the American Revolution.

Mr. Witten decided on an engineering career at an early age and even acquired the special interest in bridges which he retained through life while still an undergraduate at the University of Missouri, in Columbia. To become a bridge designer in the shortest possible time, he left the university in his senior year to work for the consulting engineering firm of Waddell and Harrington. He remained with this firm and its successor, Harrington, Howard and Ash, as draftsman, designer, and resident engineer until April, 1918. His work included the designing and supervision of construction of heavy bridges of steel and reinforced concrete, including heavy movable spans. Some of the more interesting bridges which he helped to design were the Twelfth Street Trafficway Viaduct, Central Avenue Viaduct, and other important bridges at Kansas City; the Arroyo-Seco Viaduct, Pasadena, Calif.; the North Hill Viaduct, Akron, Ohio; the Willamette River Bridge, Portland, Ore.; the Arkansas River Bridge at Tulsa, Okla.; the Colorado River Bridge at Austin, Tex.; and bascule bridges in Miami, Fla.

---

[1] Memoir prepared by Emmett H. Karrer, Assoc. M. Am. Soc. C. E.

Mr. Witten was resident engineer on the construction of the Eleventh Street Bridge across the Arkansas River in Tulsa. Impressed by the rapid growth of the city, he established the engineering firm of Wood, Elston and Witten in Tulsa in April, 1918. He remained a member of this firm and of its successor, Wood and Witten, specializing in location, design, and supervision of construction of highways, bridges, and municipal pavements, and in occasional special surveys and reports, until 1935. Among the more important projects on which the firm was engaged during this period were concrete highways and bridges for Washington County, Oklahoma, and Montgomery County, Kansas; the Twenty-Third Street Bridge over the Arkansas River in Tulsa; the Third Street Viaduct in Tulsa; and the widening of the Eleventh Street Bridge, which had been built originally under his supervision.

Mr. Witten joined the staff of the U. S. Public Roads Administration in 1935, and he was assigned to the District Six Office in Fort Worth, Tex. He acted as chief analyst for the Public Roads Administration on the design of the bridge across the Mississippi River at Baton Rouge, La. In 1938 he was transferred to District Ten in Washington, D. C., and for several years was in charge of the bridge division of that district, supervising the building of federal-aid bridges in Delaware, Maryland, Ohio, Pennsylvania, and the District of Columbia.

During the thirty-two years of his engineering career, Mr. Witten devoted practically all his time and energy to his specialty, bridge design. Entering that field when concrete design was in its infancy, he followed its development through the years, being a pioneer in many ideas which have become standard practice. He was an excellent structural analyst, and his decisions on engineering matters were characterized by sound common sense and good judgment. His joy in his work was one of his outstanding characteristics. His vocation was his avocation.

On June 11, 1914, he was married to Margaret Elston. Mr. Witten is survived by his widow; a daughter, Sarah Caroline Witten; a son, Thomas A. Witten (Captain, U. S. Army Medical Corps); a grandson, Thomas A. Witten, Jr.; and a sister, Hazel Witten.

Mr. Witten was a member of the Unitarian Church, the Rotary Club of Tulsa, and Phi Kappa Psi fraternity. His genial personality, backed by a keen sense of humor which he judiciously used, made him very popular with his fellow workers, professional associates, and many friends.

Mr. Witten was elected an Associate Member of the American Society of Civil Engineers on September 10, 1918, and a Member on October 22, 1924.

JOSEPH HENRY YOUNG, M. Am. Soc. C. E.[1]

DIED JANUARY 21, 1944

In the death of Joseph Henry Young, the State of Utah, the United States Public Roads Administration, and the field of highway engineering lost a prominent and active man who was endowed with a sixth sense—a requisite for deciding upon highway locations or revisions of existing highways. Mr. Young's work was outstanding and was greatly appreciated by the Utah State Highway Department.

Joseph Henry Young, a native son of Massachusetts, was born in Boston on February 12, 1874. He came from old American stock, his father having been a veteran of the Civil War. He attended grade school and the Dorchester High School in Boston. To further his education, he enrolled in college extension classes, including those of the University of Wisconsin at Madison. It was one of Mr. Young's great regrets that he did not receive a college degree —as a matter of fact, natural ability is of more importance than technical training when deciding highway locations.

In September, 1892, Mr. Young began his engineering career. Throughout his lifetime he continued to work on engineering projects, except during World War I, at which time he was an inspector of ordnance in a government arsenal.

His experience was rather diversified, including aqueduct and reservoir construction for the Commonwealth of Massachusetts and barge canal construction for the State of New York. He also was employed on highway work by the New York State Highway Department.

In April, 1918, Mr. Young joined the United States Bureau of Public Roads and from that time until his death served as a highway engineer in the government service. He received marked credit for his outstanding ability, which was recognized by his principals as well as by the several chief engineers serving the State of Utah during this period.

A Past-President of the Intermountain Section of the Society, he was also president of the Ogden (Utah) Engineers Club. He was a Mason and was active in civic affairs.

Mr. Young's outstanding characteristic was his generosity. Although never a man of considerable means, he contributed to many charities. Throughout the economic depression, he employed many workmen rather than have them jobless. He lost heavily by this philanthropy. To many others he gave food and shelter, and sent them on their way with increased hope and vigor. Mr. Young started many businesses, several of which benefited others rather than himself.

Always a good companion on the long inspection trips throughout Utah, he never lost his sense of humor and obtained joy from the little things of life.

---

[1] Memoir prepared by a Committee of the Intermountain Section consisting of O. C. Lockhart, M. Am. Soc. C. E., R. R. Mitchell, Assoc. M. Am. Soc. C. E., and R. E. Simpson, Jun. Am. Soc. C. E.

In all his contacts with others he was courteous and dignified, and commanded the respect and esteem of brother engineers.

On September 17, in Marlboro, Mass., he was married to Minnie Adler. Mr. Young is survived by his widow and a son, Carleton Young (Captain, U. S. Army Air Forces).

Mr. Young was elected a Member of the American Society of Civil Engineers on November 15, 1926.

ELISHA BROWN BAKER, Assoc. M. Am. Soc. C. E.[1]

DIED JULY 12, 1942

Elisha Brown Baker was born in Kingsboro, N. Y., later a part of the City of Gloversville, N. Y., on March 6, 1870, the son of Manville Cook Baker and Harriet (Brown) Baker. He was graduated from Union College at Schenectady, N. Y., in 1890, with the degree of Civil Engineer. In college he was a member of Delta Phi fraternity and in his senior year was elected to the scientific society of the Sigma Xi.

After his graduation, Mr. Baker served for a time as clerk for the Board of Water Commissioners and later as city engineer of Gloversville. In 1897 Mr. Baker began his career as a contractor. In partnership with Albert M. Banker of Gloversville, he entered into a contract for the improvment of the Erie Canal at Middleport, N. Y. Upon completion of that work in 1898, Mr. Baker went to Pittsburgh, Pa., and, from 1898 to 1907, he built locks and dams on the Ohio and Monongahela rivers.

In 1907 he returned to Schenectady to begin construction on the first of a long series of contracts for parts of the New York State Barge Canal. For twenty-five years, Mr. Baker was actively engaged as a contractor, building many locks, dams, and other structures on the Canal, chiefly along the Mohawk River from Cohoes, N. Y., to and including the terminal at Utica, N. Y. He also was awarded many other contracts for state highways and other public projects.

In 1932 Mr. Baker retired from active work as a contractor, but after that date he served for a time as assistant city engineer of Utica and as a member of the Municipal Civil Service Commission of Utica.

On November 28, 1906, Mr. Baker was married to Sarah Pfeil, of Pittsburgh. Mrs. Baker and a daughter, Elizabeth Brown Baker, survive him.

Mr. Baker was a trustee of Westminster Church, in Utica. He was a Thirty-Second Degree Mason, and a member of the Fort Schuyler Club, the Torch Club, and the Yahnundasis Club of Utica; and the National Society of Professional Engineers.

Mr. Baker was elected an Associate Member of the American Society of Civil Engineers on April 1, 1896. He became a Life Member in 1931.

---

[1] Memoir prepared by Frederick W. Newton, Assoc. M. Am. Soc. C. E.

ERNEST DANIEL BEAN, Assoc. M. Am. Soc. C. E.[1]

DIED FEBRUARY 20, 1943

Ernest Daniel Bean was born at Haverhill, Mass., on July 13, 1884, the son of John Ames and Henrietta (Brown) Bean. He was educated in the public schools of Haverhill, and the University of Maine at Orono, from which he was graduated in 1907 with the degree of Bachelor of Science in Civil Engineering. He made an enviable record in athletic and social activities.

As with most engineers, his professional career started with minor positions during college vacations and continued thereafter in successive engagements of increasing responsibility. By 1911 he had progressed to general superintendent for Barrally and Ingersoll on a three-mile section of the New York State Barge Canal. Following the completion of this work, he became chief engineer of the Palisades Interstate Park Commission and supervised design and construction on this 35,000-acre playground until early in 1915. In 1917 Mr. Bean was superintendent for W. R. Phillips Company and directed construction on a plant for 6-in. guns at Fairfield, Conn.

After several years of diversified engagements on construction and appraisal work, he joined the J. G. White Management Corporation as hydraulic engineer in 1923 and for fifteen years continued in this field with that company and its successor, the Associated Gas and Electric Company. During this period he worked on many hydroelectric installations—sometimes as designer, sometimes as supervisor, sometimes as construction superintendent, and not infrequently as all three. The project which gave him the greatest satisfaction was the 16,000-kw development at Botocan near Manila, Philippine Islands. As chief engineer of construction, he spent two years during 1929–1931 building this $5,000,000 project which involved a concrete dam, 4,000 ft of rock tunnel, and a power house in which water under a 647-ft head motivated the equipment. The plant was flooded in 1934 when 27 in. of rain fell on the watershed within a few days. Mr. Bean spent most of 1935 at Botocan, devising, designing, and constructing the necessary diversion and protection works.

From July, 1938, to July, 1940, he served as engineer, senior engineer, and expert hydraulic engineer to the Power Division of the Public Works Administration and the Federal Power Commission, investigating the possibilities of many hydraulic development projects and several phases of the Shasta (California), Santee-Cooper (South Carolina), and Tennessee Valley Authority developments.

After a brief engagement on cantonment construction at Starke, Fla., he was employed by the Hercules Powder Company as supervising engineer in January, 1941, and directed construction of that company's $12,000,000 ordnance plant at Pulaski, Va. Late in 1941, when this plant was substantially completed, poor health forced him to resign.

---

[1] Memoir prepared by Cuyler W. Lush, M. Am. Soc. C. E.

Twice in 1942—once with the Rust Engineering Company and once with the Tuller Construction Company—he resumed active work with his customary enthusiasm; but each time failing health forced his resignation in a few months.

Known to his friends as "Beano," Mr. Bean possessed the happy faculty of making whatever work was at hand a pleasure for his fellow workers. Many were the testimonials given to him by associates on various engagements and many are the pleasant memories of his genial humor and good cheer which linger with those who knew him. He was a Protestant, a Mason, and a member of the Phi Eta Kappa society.

He was married on July 17, 1909, to Beth E. Hoyt.

Mr. Bean was elected an Associate Member of the American Society of Civil Engineers on October 1, 1912.

FRANK JOSEPH BOYLE, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 20, 1944

Frank Joseph Boyle was born in Hazleton, Pa., on June 3, 1896, the son of Patrick M. and Bridget (Moore) Boyle.

His early education was received in the grade schools of Wilkes-Barre, Pa. He attended the Mining and Mechanical Institute in Freeland, Pa., and, in September, 1914, he entered Pennsylvania State College, in State College. At the end of his junior year, since the United States had entered World War I, Mr. Boyle decided to join the Army, and he enlisted on August 15, 1917, at Madison Barracks, in Watertown, N. Y. After a training period, he was commissioned a Second Lieutenant in the Signal Corps and was transferred to Fort Omaha, Nebraska, where he served as an instructor in aerial artillery observation and map reading. He received his discharge on January 16, 1919, at Camp Grant, Ill. In the fall of 1919, he reentered Pennsylvania State College and received the degree of Bachelor of Science in Sanitary Engineering in June, 1920.

In 1913 Mr. Boyle began his engineering career, working as a rodman and chainman on a surveying party for L. S. Howe, of Kingston, Pa. After graduation from college, he worked for two years as transitman and chief of party on general engineering surveys. From September, 1922, to April, 1931, he was associated with his brother, the late James A. Boyle, Assoc. M. Am. Soc. C. E., in Wilkes-Barre, on sewerage systems and highways for various municipalities and townships and on the construction of roads, sewers, and bridges for the Pennsylvania Highway Department.

From June, 1931, to January, 1936, Mr. Boyle was employed as assistant engineer by Luzerne County (Pennsylvania) on the design of steel and concrete bridges. From February, 1936, to October, 1938, he served as construction superintendent for the Works Progress Administration in the Wilkes-Barre District in charge of the bridge program. From November, 1938, to September, 1940, he was resident inspector for the Public Works Administration in the Pittsburgh (Pa.) District. In November, 1940, Mr. Boyle accepted a position as designer in the Bureau of Design of the Allegheny County (Pennsylvania) Department of Works, checking final estimates on bridge construction.

---

[1] Memoir prepared by R. S. Quick, M. Am. Soc. C. E.

Mr. Boyle was well liked by his associates. At all times he showed a willingness to assist others with their problems. His experience in the Air Corps in World War I made him keenly interested in the progress of aviation during World War II. He was very proud that two of his sons were in this branch of the service—one as Second Lieutenant in the Army Air Corps and the other as Ensign in the Navy Air Corps.

On January 20, 1920, Mr. Boyle was married to Martha Seitzinger. His widow and three sons, Richard J. (Second Lieutenant, U. S. Army Air Corps), James (Ensign, U. S. Navy Air Corps), and Frank Joseph, Jr., survive him.

Mr. Boyle was elected an Associate Member of the American Society of Civil Engineers on November 9, 1942.

THOMAS BYRNES BROGAN, Assoc. M. Am. Soc. C. E.[1]

Died June 11, 1944

Thomas Byrnes Brogan was born in New York, N. Y., on July 4, 1880, the son of John J. Brogan and Maria (Fence) Brogan.

He received his early education in New York City at Public School No. 3 in Greenwich Village and the Dwight School. In 1903 he was graduated from New York University with the degree of Bachelor of Science in Civil Engineering.

During the summer of 1902 he worked as instrumentman for the Erie and Central New York Railroad Company. From July, 1903, to January, 1904, he was employed as instrumentman by C. Robinson Griggs in New York City. In 1905 he became map draftsman and field topographer for E. Belcher Hyde. He was in charge of shield-driven tunnels in compressed air from July, 1905, to September, 1909, and was responsible for line and grade as tunnel inspector at the Weehawken (N. J.) Shaft of the Pennsylvania Railroad Tunnels.

Entering the employ of the City of New York, from October, 1909, to May, 1913, he was employed as engineer inspector and assistant engineer on the construction of the Catskill Aqueduct for the Board of Water Supply. From May, 1913, until his death, Mr. Brogan was connected with the Bureau of Highways—later the Bureau of Highways and Sewers—in the office of the President of the Borough of Brooklyn, City of New York. Until 1922 he was engaged on surveys for all highway improvements in that borough, and, from 1938 to 1941, he was in charge of construction of all highway improvements in the southerly and easterly sections of Brooklyn. From 1941 until his death he was in charge of the preparation of final estimates for all highway work of the Bureau. While on active field duty, Mr. Brogan suffered a heart attack and died after three days of illness.

---

[1] Memoir prepared by Joseph C. O'Dea, Assoc. M. Am. Soc. C. E.

Mr. Brogan was a quiet, unassuming gentleman. He was always kind and considerate and enjoyed the affection and respect of those who were associated with him. He was conscientious and painstaking in all his efforts.

In 1912, he was married to Bertha Melius who died in 1920. He is survived by a brother, John J. Brogan, and a sister, Mrs. Edward F. Faulkner.

Mr. Brogan was a member of the Delta Upsilon fraternity and the New York Lodge, F. and A. M.

Mr. Brogan was elected an Associate Member of the American Society of Civil Engineers on February 1, 1910.

WALTER JOHN BUCHANAN, Assoc. M. Am. Soc. C. E.[1]

Died August 14, 1944

Walter John Buchanan, the son of Peter and Margaret (Pender) Buchanan, was born at Hamilton, Scotland, on October 31, 1888. He was educated at Allan Glen's School, in Glasgow, Scotland, and at the Royal Technical College of the University of Glasgow, from which he obtained an Associateship in Civil Engineering and a Diploma in Mining Engineering.

After spending several years with the firm of Sir Robert McAlpine and Sons, in 1915 he joined the staff of the late Prof. T. Gray at the Royal Technical College. In this capacity, he assisted in the toluene control for Scotland during World War I.

In 1919 he was appointed to the teaching staff of the Royal Technical College and was largely responsible for the supervision of the Fuel Laboratories until his death. For many years he endeared himself to his colleagues by his genial disposition and to his students by the painstaking assistance he rendered them in their practical work.

Mr. Buchanan was well known in Glasgow and was a keen golfer. He was a bachelor and is survived by three brothers and a sister.

Mr. Buchanan was elected a Junior of the American Society of Civil Engineers on April 30, 1912, and an Associate Member on July 6, 1920.

---

[1] Memoir prepared by W. M. Cumming, "Young" Prof. of Technical Chemistry, The Royal Technical College, Glasgow, Scotland.

EDWARD LARAMIE CARPENTER, JR., Assoc. M. Am. Soc. C. E.[1]

Died July 18, 1943

Edward Laramie Carpenter, Jr., was born at Vancouver, Wash., on March 3, 1900, the son of E. L. Carpenter, and Harriet (Brown) Carpenter. He was educated in the public schools of Aberdeen, Wash., and was graduated from the University of Washington at Seattle in 1924 with the degree of Bachelor of Science in Civil Engineering.

Edward Carpenter's boyhood was spent near or on engineering projects in the Pacific Northwest which were under the direction of his father, a senior civil engineer with the U. S. Engineer Department. This early experience, coupled with his technical engineering training, equipped him for his chosen field of general contracting.

In 1924, immediately after graduation, Mr. Carpenter entered the employ of the Wallace Bridge and Structural Steel Company of Seattle, first as steel designer and later as squad leader in the drafting room. In 1927 he was promoted to resident engineer, and served in that capacity on several important steel erection jobs, including the Spokane Street Bridge, the Northern Life Tower, and the Washington Athletic Club, all in Seattle; the Longview Bridge at Longview, Wash., across the Columbia River; and the St. John's Bridge at Portland, Ore.

In 1930 Mr. Carpenter joined the contracting firm of Henry and McFee, and assisted in the construction of a large repair and outfitting pier at the Puget Sound Navy Yard, Bremerton, Wash. He then became assistant superintendent for the same organization on the construction of a large reinforced concrete pier for the American Can Company at Seattle.

In 1931 he returned to the employ of the Wallace Bridge and Structural Steel Company as resident engineer in charge of steel erection for the dirigible hangar at the Naval Air Station at Sunnyvale, Calif., one of the largest structures of its kind in the world.

In 1932 Mr. Carpenter became associated with the Puget Sound Bridge and Dredging Company of Seattle, a pioneer construction organization of the Northwest. His first duties were as superintendent of construction of a rock mound breakwater for Santa Monica, Calif., followed by a similar position on the construction of the first unit of the San Pedro (Calif.) detached breakwater. For the ensuing ten years, as a member of the Puget Sound Bridge and Dredging Company organization, Mr. Carpenter had responsible charge of many other large and important construction projects throughout the Pacific Coast States and Alaska, included in which were the improvement of Cordova Harbor and dredging in Wrangell Narrows, Alaska. He was assistant superintendent on the construction of the Lake Washington Floating Bridge at Seattle, the largest floating bridge in the world; and superintendent in charge of field construction of a large U. S. Naval Air Station at Kodiak, Alaska, a work of unusual responsibility and magnitude.

---

[1] Memoir prepared by H. W. McCurdy, M. Am. Soc. C. E., and J. Adron Troxell, Jun. Am. Soc. C. E.

In January, 1942, Mr. Carpenter was called into active service in the U. S. Naval Reserve with the rank of Lieutenant Commander, and was assigned to the Admiral's staff in the Alaska Sector. The following July, he was killed in an airplane crash while on an inspection trip.

Commander Carpenter was a man of fine character, an engineer and contractor of extremely wide experience, and a thoroughly capable operator and organizer.

On August 7, 1924, in Seattle, he was married to Margaret Kamps. He is survived by his widow, Margaret; two children, Margaret Jean and Edward; his mother, Mrs. H. H. Kamps; and a sister, Frances (Mrs. Loren H. Holden).

Commander Carpenter was elected an Associate Member of the American Society of Civil Engineers on November 27, 1933.

ROBERT PICKET CARR, Assoc. M. Am. Soc. C. E.[1]

Died February 23, 1945

Robert Picket Carr, the son of Albert and Josie (Butterfield) Carr, was born at East Orange, N. J., on January 17, 1896. After attending the East Orange High School and the Peddie School in Hightstown, N. J., he spent two years at Lafayette College in Easton, Pa.

When the United States entered World War I, he tried to enlist, but an old injury to his back caused his rejection. For nearly a year he worked for International Coal Products Company in Newark, N. J. In June, 1918, he was drafted by the U. S. Army, and went to Edgewood, Md., in the Chemical Warfare Service. His final rating was Sergeant First Class. In December, 1918, he was honorably discharged from the Army.

After a few months in Cincinnati, Ohio, in 1919 Mr. Carr went to Michigan College of Mining and Technology at Houghton, being graduated in 1921 with two degrees—Bachelor of Science and Engineer of Mines. His first mining experience was with Chontales Mines, Ltd., at Santo Domingo, Nicaragua, as mine engineer and shift boss. In 1922 he was employed by the Braden Copper Company in Rancagua, Chile, and remained three years. During 1923 and 1924, he served as safety engineer for the entire property. In 1925 he worked on the exploration, tunneling, etc., of two proposed mines in Chile.

In 1926 he was employed by Cia Chilena de Electricidad of Santiago, Chile. He remained with this company for eight years, serving in several very important capacities. For six years he was foreman of the construction department, chief of transport, and superintendent of work on hydroelectric plants, transmission lines, and concrete buildings. He rose to the position of assistant chief engineer, and became acting chief engineer when the chief engineer, A. C. Sandstrom, M. Am. Soc. C. E., died very suddenly on August 4, 1929. During his last years with the company, he concentrated on general office work and special reports.

---

[1] Memoir prepared by Mrs. Albert Carr, East Orange, N. J.

In 1935 Mr. Carr was called to Oruro, Bolivia, by the International Machinery Company, as manager for Bolivia, continuing in that position for six years. In addition to regular work on industrial and electrical equipment, he handled all government priorities. In 1941 he was employed as technical adviser by the large mining and industrial organization of M. Hochschild and Company. At the end of his three-year contract, in the autumn of 1944, he went to New York, N. Y., for a few months, but decided to accept another contract with the same company; and, in January, 1945, he left New York for Lima, Peru, where he died on February 23, 1945.

On January 16, 1926, Robert Carr was married to Tulia Ehijo, of San Bernardo, Chile. He is survived by his widow and three daughters, Jacqueline del Carmen Carr, Josie Maria de la Luz Carr, and Marie Angelica Carr.

He was a member of the American Institute of Mining Engineers and the Trinity Congregational Church of East Orange. In a letter, a fellow engineer in Chile testifies to Mr. Carr's fidelity, industry, indomitable perseverance, and conscientious effort to produce the best possible results.

Mr. Carr was elected an Associate Member of the American Society of Civil Engineers on November 11, 1929.

DAVID WILSON CROFOOT, Assoc. M. Am. Soc. C. E.[1]

DIED SEPTEMBER 20, 1944

David Wilson Crofoot, the son of George L. and Mary A. (Thomas) Crofoot, was born on January 3, 1902, in Vandling, Pa. He was graduated from Cornell University at Ithaca, N. Y., in 1923 with the degree of Bachelor of Arts.

His first engineering employment after graduation was with the Pennsylvania Department of Highways as draftsman and inspector. From October, 1925, to October, 1929, he served the Alabama Highway Department as transitman, party chief, and resident engineer. In October, 1929, he entered the employ of the Missouri Highway Department as designer and later was promoted to project engineer. In February, 1942, he was appointed construction office engineer in Joplin, Mo.

On November 22, 1942, he enlisted in the United States Army. Later he was commissioned a Second Lieutenant in the Corps of Engineers and was in action on Angaur Island in the central Pacific area when he received the wounds which caused his death on September 20, 1944.

---

[1] Memoir prepared by a Committee of the Kansas City Section consisting of Chester A. Smith, M. Am. Soc. C. E., and E. A. Blanpied, Assoc. M. Am. Soc. C. E.

Lieutenant Crofoot was a cultured, refined Christian gentleman of pleasing personality, always quiet, reserved, and considerate of others. He was ambitious and his work was his first concern, but he spent his spare time reading and studying which made him exceedingly well versed in many subjects.

On June 29, 1929, in Clayton, Ala., he was married to Helen Clayton Quillin. He is survived by his widow.

Lieutenant Crofoot was elected a Junior of the American Society of Civil Engineers on November 11, 1929, and an Associate Member on April 25, 1932.

LUIS AGUSTIN DELIZ, Assoc. M. Am. Soc. C. E.[1]

Died February 17, 1944

Luis Agustin Deliz was born in the Town of Aguadilla, Puerto Rico, on May 5, 1890, the son of Jose M. Deliz and Ana P. (Mendez) Deliz.

After receiving his early schooling in his home town, he continued his education in the United States, entering Baltimore (Md.) Polytechnic Institute from which he was graduated in 1909. He later studied engineering at Lehigh University in Bethlehem, Pa. In 1923 he received the degree of Bachelor of Science in Civil Engineering from the University of Puerto Rico at Rio Piedras.

From 1911 to 1920 Mr. Deliz worked at intermittent periods for the insular government of Puerto Rico in various capacities—as transitman, inspector, and assistant chief engineer in charge of design and construction of various public works. In 1920 he accepted a position as assistant engineer with the American Railroad Company of Puerto Rico. From 1926 until 1929, he was superintendent of public works for the City of San Juan, Puerto Rico. In this capacity he supervised the construction and maintenance of all streets, municipal roads, water works, public buildings, etc.

From 1930 until his death, Mr. Deliz held various positions—assistant engineer with James H. Fuertes,[2] M. Am. Soc. C. E., of New York, N. Y.; assistant engineer, Board of Transportation, New York City; designing engineer, Department of the Interior of Puerto Rico; assistant chief, Bureau of Translation of the Government of Puerto Rico; and assistant engineer, U. S. Engineer Department, San Juan.

In addition to his engineering work, Mr. Deliz was engaged throughout his life in other activities and civic affairs. His unusual ability as a translator and his knowledge of Spanish and English made him valuable as assistant chief of the Bureau of Translations of the Government of Puerto Rico. He was an active and prominent Mason and was worshipful master of the Estrella de Luquillo Lodge No. 5. He was for some time president of the charitable society, Shoes for Poor Children, and was a prominent member of the political party, Union Republicana, advocating the granting of statehood to the Island of Puerto Rico by the Congress of the United States.

---

[1] Memoir prepared by Etienne Totti y Torres, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 96 (1932), p. 1482.

Mr. Deliz belonged to the Sociedad de Ingenieros de Puerto Rico and the Institute of Engineers of Puerto Rico. He was an active member of the Puerto Rico Section of the Society, serving as Secretary-Treasurer and as Vice-President. His activity and zeal contributed much to Society affairs.

Mr. Deliz died at a time when he could have been of most service to Puerto Rico. His sense of civic duty and responsibility added to his quiet and simple manners and his ability to make friends made those who knew him feel that a valuable citizen had been lost.

In 1920 in Yauco, Puerto Rico, Mr. Deliz was married to Mary Roig. He is survived by two sons, Luis R. Deliz and Norris E. Deliz.

Mr. Deliz was elected an Associate Member of the American Society of Civil Engineers on February 10, 1930.

CARL E. DOWNING, Assoc. M. Am. Soc. C. E.[1]

DIED FEBRUARY 27, 1942

Carl E. Downing was born at Perlee, Iowa, on November 1, 1884, the son of Philip Henry and Ermina (Snook) Downing. He was graduated from the State University of Iowa at Iowa City in 1911 with the degree of Bachelor of Engineering, and in 1915 he was awarded the professional degree of Civil Engineer by his alma mater.

In 1911 Mr. Downing entered the employ of the Morgan Engineering Company in Memphis, Tenn., and remained with that company as rodman and instrumentman for a year and a half, except for two months spent with the Chicago Rock Island and Pacific Railway Company as masonry inspector.

From December, 1912, until November, 1918, he was employed by the Belzoni Drainage District at Belzoni, Miss. After about a year as assistant engineer, he became chief engineer on the construction of a large flood control and drainage project for the reclamation of agricultural land.

For a short time in 1919, Mr. Downing was assistant engineer with the U. S. Reclamation Service in Wyoming. For nearly three years, during two periods—first in 1919 and again in 1921 and 1922—he conducted a private engineering practice at Belzoni, and also served as chief engineer for the City of Belzoni and as engineer for surrounding towns and communities on the construction of sewer, street paving, road, and drainage projects.

In May, 1919, he entered the employ of the Mississippi State Highway Department and, with the exception of about two years as city engineer of Belzoni and in private practice, remained with this department until January, 1940. For five years he served as project engineer on road construction, for one year as assistant district engineer, and for nearly thirteen years as district engineer in charge of road construction and maintenance, with headquarters first at New Albany, then at Holly Springs, and finally at Oxford, Miss. The most important work of his career was done for the Mississippi Highway Department. During this period the State of Mississipi constructed an extensive state-wide system of modern paved highways, and Mr. Downing's sound engineering judgment and integrity were largely responsible for the excellent system of roads in northern Mississippi.

---

[1] Memoir prepared by Leroy L. Hidinger and Lee H. Johnson, Jr., Members, Am. Soc. C. E.

During 1940 and 1941 he was employed by the Work Projects Administration as project engineer and superintendent in charge of work on roads and city streets for Oxford and near-by communities.

Mr. Downing was a quiet, steady, efficient engineer and a man of sterling character, highly respected by his associates and in the communities where he lived. Although his personal life was quiet and unassuming, he left a favorable lasting impression on all those with whom he came in contact.

On July 14, 1920, Mr. Downing was married to Edna Armstead Southall of Belzoni. He is survived by his widow; a daughter, Patricia Armstead Downing; and a son, Carl Seldon Downing.

Mr. Downing was elected a Junior of the American Society of Civil Engineers on October 1, 1913, and an Associate Member on December 6, 1915.

CHARLES DORMAN EVANS, Assoc. M. Am. Soc. C. E.[1]

DIED JUNE 30, 1944

Charles Dorman Evans was born in Galveston, Tex., on June 19, 1879, the son of Charles and Mary Cecile (Chambers) Evans.

His high school education was completed at Bicker Academy, in Austin, Tex., and he was graduated from the Agricultural and Mechanical College of Texas at College Station in 1899 with the degree of Bachelor of Science in Civil Engineering.

Most of his early professional experience was in railroad work. After working a few months as architectural draftsman immediately after graduation from college, Mr. Evans started as chainman on railroad location and construction, progressing successively through various field and office engineering positions to chief engineer. His railroad experience was gained with various branches of the Southern Pacific Railroad Company, the Louisiana Railway and Navigation Company, and the International and Great Northern Railway Company. With the exception of intermittent periods while employed on other work, Mr. Evans continued on railroad location, design, construction, and maintenance through 1913. During this time he had the opportunity to design not only the necessary engineering structures but also the more complicated structures, such as depots, warehouses, coaling stations, freight terminals, and other similar units.

---

[1] Memoir prepared by Elmer L. Ferguson, Clovis J. Harkrider, and R. L. Tatum, Assoc. Members, Am. Soc. C. E.

After a short period in private practice, Mr. Evans assumed the management of a 1,500-acre plantation. His engineering education, knowledge, and background were of material benefit in enabling him not only to design a complete water pumping plant and distribution system and other necessary improvements, but also to establish a type of management which resulted in a profitable self-supporting concern.

In 1919 he again entered private engineering practice as senior member and manager of the engineering firm of Evans and Buxton at Shreveport, La., and in 1921 he became sole owner of the firm. His practice included design and supervision of water supply and distribution systems, sanitary sewer systems and disposal plants, steel and reinforced concrete bridges, storm sewers, street paving, reclamation and drainage, land developments, athletic fields and campus improvements, landscaping, oil field surveys, tank-farm layouts, pipe-line locations, investigations and reports, court evidence, and similar work in north Louisiana, south Arkansas, and east Texas.

In 1930 Mr. Evans was elected city commissioner of Shreveport, and served in both this capacity and as superintendent of streets and parks for two successive terms until 1934. Besides the regular duties normally indicated by his title, he had charge of the planning and maintenance of a municipal airport and made an extensive study of the garbage collection and disposal problem of the city, resulting in the construction of a modern incinerator.

During the early part of 1941 he was chief engineer for the Louisiana State Conservation Department in charge of design and construction of park improvements in coordination with the National Park Service, including water systems, sewer systems, beach improvements, roads, and bridges. For a short time before beginning these duties, he was superintendent of construction on a four-story hospital and several other masonry buildings.

Mr. Evans started service with the federal government early in life as civil engineer with the Bureau of Yards and Docks, at the New Orleans (La.) Naval Station for a short period in 1904. He again entered government service in 1935 as resident engineer inspector with the Public Works Administration, and continued in that capacity through April, 1940. He represented the federal government on the supervision of several large sewage collection systems and treatment plants, drainage structures and canals, pumping and power plants, and numerous public buildings of various types.

When Congress passed the Community Facilities Act in furtherance of the defense and war efforts early in 1941, the services of Mr. Evans were requested to assist in the reorganization of the former Public Works Administration to administer the funds appropriated to carry out the purposes of the act. Although his permanent civil service status would have been placed in jeopardy if he did not return to government service before July 1, 1941, Mr. Evans insisted upon delaying acceptance of the appointment until his former employer could be given sufficient notice to permit his replacement. This action is typical of Mr. Evans' fairness in his relationships with other people.

From August, 1941, until his death he served as examining engineer and senior examining engineer for the Public Works Agency which was later designated as the Federal Works Agency. In this capacity, he made investigations of complicated prospective projects to determine need and scope. He also assisted in the construction from inception of the plans to completion of the work. His broad and versatile experience enabled him to handle a wide variety of projects.

Mr. Evans was a member of the First Presbyterian Church of Shreveport and had been a deacon for many years. He was also a Knight Templar, but liked his home too much to be a very regular attendant at lodge meetings. He belonged to the Louisiana Engineering Society.

A great lover of the outdoors, Mr. Evans fished and hunted all his life. He knew the names and habits of all the southern birds, and was an expert taxidermist in his youth. He loved all growing things—his garden was full of plants and vines from places he had visited. Art was another of his avocations, and it was his ambition to paint. In 1939 he joined an art club and painted several excellent landscapes in pastels. He also collected coins and had a very good collection of old firearms.

Mr. Evans was an excellent engineer and a man of fine personality and high ideals. His standing in Shreveport, where he had maintained residence since the beginning of the century, was the best. He was highly esteemed as an efficient and accommodating public servant, and his loss is deeply regretted by his many friends.

On November 7, 1912, in Shreveport, La., he was married to Nell Taylor. He is survived by his widow; one daughter, Genevieve (Mrs. A. F. Merewether); four grandchildren, Diana Genevieve, Catherine Evans, Frances Charles, and James William Merewether; a sister, Mrs. Cecile Oliphant; and three brothers, Stanley, W. C., and J. P.

Mr. Evans was elected an Associate Member of the American Society of Civil Engineers on March 7, 1921.

LOUIS FOCHT, Assoc. M. Am. Soc. C. E.[1]

DIED JUNE 4, 1944

Louis Focht, the son of Hiram and Georgette (Rex) Focht, was born in Elizabeth, N. J., on September 5, 1863. He attended Lehigh University at Bethlehem, Pa., where he studied civil engineering.

In 1883 he entered the engineering department of the Lehigh Valley Railroad Company, as rodman, when that company was emerging from the status of a local railroad to that of a trunk line, actively engaged in extensive construction. He remained with the Lehigh Valley Railroad Company until 1897, during the last ten years acting as division engineer in charge of all construction and maintenance on the New Jersey, Lehigh, and Pottsville divisions.

---

[1] Memoir prepared by Edwin W. Denzler, Jr., Assoc. M. Am. Soc. C. E.

During this period Mr. Focht worked on the location and construction of the main line from South Plainfield, N. J., to Newark Bay, New Jersey, and the Raritan River, Flemington, Pittstown, and Bloodgood branches. Under his supervision, the Musconetcong Branch was extended by constructing a dam on the Musconetcong River, coal and freight docks, and terminal yard facilities at Perth Amboy, N. J., and relining the Musconetcong Tunnel. Also, he constructed and operated a creosoting plant at Perth Amboy and a coal storage plant at South Plainfield. He was engaged actively in the location and construction of a connection for the Easton and Northern Railroad Company at Easton, Pa., including the design and construction of a new bridge across the Lehigh River. He had charge of maintenance of way for the Lehigh Valley Railroad Company from Pottsville, Pa., and Pennhaven Junction, Pennsylvania, eastward to Newark and Perth Amboy, covering both main line and branches, including property of the Pennsylvania, Poughkeepsie and Boston Railroad (later a part of the Lehigh and New England Railroad Company). In addition, Mr. Focht acted under special assignment on the investigation of many new projects, one of which was a new independent railroad line from Buffalo, N. Y., to Toledo, Ohio.

In 1897 he resigned from the Lehigh Valley Railroad Company to become chief engineer of the Lehigh Construction Company, at that time constructing a large hydroelectric power development on the St. Lawrence River. He remained with this company until May, 1898. Mr. Focht then became engineer for the State Board of Assessors of New Jersey. In this connection, from that time until his death, he valued all railroad property in the state for assessment purposes, with different titles and in the employ of various boards, such as the State Board of Assessors, the State Board of Taxes and Assessment, and the State Tax Department. From 1910 to 1912 he acted as chief engineer in charge of revaluation of all railroad and canal property in New Jersey. From 1931, when the State Tax Department was created, he was director and chief engineer, in charge of the Division of Engineering and Railroad Taxes.

On special assignment, Mr. Focht spent some time in Venezuela and Colombia, South America, investigating the Táchira Railroad, for a syndicate of American bankers. This assignment included reconnaissance work from Lake Maracaibo to the valley of the Orinoco River and a report on the cost, probable traffic, income, and other problems pertaining to the economics of the project, during 1897. In 1901–1902 he acted as chief engineer and superintendent on construction and operation for the New Jersey Terminal Railroad Company. In 1907 he was chief engineer of the Mount Desert Railway Company, in Maine, making preliminary surveys, locations, estimates, and designs of railway structures. The panic of 1907 resulted in the suspension of this project. From 1912 to 1914 he was consulting engineer of the Virginia Products Corporation of Baltimore, Md. In this capacity he designed factory buildings and equipment and developed an economical process for concentrating glycerine.

From 1912 to 1913 Mr. Focht was also engineer to the Godfrey (New Jersey) Legislative Commission then investigating the status of the Morris

Canal, submitting several reports covering the valuation of the property and the economical features relating to the possible enlargement of the canal. In 1923, through legislative action, he was made a member of the Morris Canal Abandonment Commission. This commission was given plenary powers by the New Jersey Legislature to enter into a compact with the Lehigh Valley Railroad Company for the abandonment of the canal property.

From 1921 until his death Mr. Focht was a member, chief engineer, and general superintendent of what was later the Delaware River Joint Toll Bridge Commission, which purchased and operated sixteen highway bridges over the Delaware River between New Jersey and Pennsylvania, from Trenton, N. J., on the south, to Milford, Pike County, Pa., on the north. During this period and under his direction, four new highway bridges were designed and constructed. In 1938 the $2,500,000 highway bridge connecting Easton and Phillipsburg, N. J., was designed and constructed under his supervision, and is operated as a toll bridge.

Louis Focht was an able engineer. He exercised good judgment and common sense at all times. He took a keen personal interest in every phase of the work being done under his supervision and, because of his wide experience, was always able to offer helpful criticism. He made many contacts and associations which resulted in lasting friendships with many men in the engineering profession, and he will be missed. As an executive, he was strict but always just. He was very quiet and unassuming and never sought publicity for himself, nor limelight for his actions. He was meticulous in all undertakings and any one having dealings with him would soon discover that he was ruggedly honest.

On November 16, 1899, in Bethlehem, Pa., Louis Focht was married to Pauline Detwiller Doster, of Bethlehem, who survives him. He is also survived by a son, Doster, and three grandsons.

He was a licensed professional engineer and land surveyor in the State of New Jersey. For five years he served as chairman of the Local Membership Committee of the Philadelphia Section of the Society, for South Jersey. Mr. Focht belonged to the American Institute of Mining and Metallurgical Engineers, the American Chemical Society, the Society of Chemical Industry of England, and the Society of American Military Engineers (life member).

Mr. Focht was elected an Associate Member of the American Society of Civil Engineers on May 4, 1892. He became a Life Member in 1927.

HOWARD LEWIS FRANCIS, Assoc. M. Am. Soc. C. E.[1]

Died December 11, 1936

Howard Lewis Francis was born at Charlevoix, Mich., on November 27, 1884. His parents were William Helson Francis, of English ancestry, and

---

[1] Memoir prepared by Verne L. Havens, M. Am. Soc. C. E. Mr. Havens died on August 12, 1944.

Christy Ann (McLean) Francis, of Scottish ancestry, both of Canadian birth. Mr. Francis was educated in the public schools of his native city and was graduated from Michigan State College in East Lansing with the degree of Bachelor of Engineering in 1906.

Two major interests in Mr. Francis' early life affected all his later activities. One was the proximity of Lake Michigan where he became an expert in the handling of catboats and other small craft. The other was an innate interest in people on both sides of the Canadian-American border and later in the peoples of other lands. Even before his graduation from college, his plans were made for a first-hand study of the history, resources, and language of the Caribbean area and Mexico, as well as of the peculiar problems of the people living there. The following record indicates Mr. Francis' professional activities:

June, 1906—Instrumentman on railroad construction with the Chicago, Rock Island and Pacific Railway Company at Moorland, La.

February 1, 1907—Draftsman, Trussed Steel Concrete Company, designing reinforced concrete structures in Chicago, Ill.

May 1, 1907— Assistant resident engineer on Long Key Viaduct of the Key West Extension of the Florida East Coast Railway Company, in charge of party responsible for measurements pertaining to construction operations.

September 1, 1907, to December 1, 1908—First assistant engineer, Department of Public Works of Cuba, during the armed intervention by United States forces; one of a commission of three to study the design of aqueducts and water distribution systems for cities in Santa Clara Province, in direct charge of surveys and assistant on design.

January, 1909—Bridge engineer, Southern Pacific Railroad Company of Mexico in charge of a 1,200-ft steel and concrete bridge over the Piaxtla River in Sinaloa; completed grading on a 12-mile residency including steam-shovel work.

January and February, 1910—Engineer in charge of subdivision of a 40,000-acre estate in Veracruz, Mexico.

March 10, 1910—Superintendent of bridges and buildings for the Mexico Tramways Company, the Mexican Light and Power Company, and related enterprises; assistant to the writer on design, inspection, and maintenance, supervising a labor force ranging from 800 to 1,200 men on various jobs worth from $10,000 to $50,000—receiving station, substations, carbarns, fire protection work, office buildings, foundations, and boiler maintenance projects. (Mr. Francis was at times required to bid against independent contractors and always to comply with building codes. The revolution led by Francisco Madero caused cessation of the work.)

July, 1912—Engineer on the writer's staff in Uruguay in connection with the Port Paloma to Cebollati Railroad of the Farquhar syndicate; in local charge of construction of the first section of the line. (Cessation of this work was caused by the Balkan War which interfered with the credit agreements between the syndicate and French bankers.)

January, 1914, to January, 1915—Independent contractor in Mexico City, Mexico.

1915 to December, 1920—Chief civil engineer of the Mexico Tramways Company under the government of Venustiano Carranza; after Señor Carranza's assassination, chief engineer of the Central Railroad of Santo Domingo and at times general manager.

October, 1921, to 1932—Independent operator engaged in various commercial enterprises; later counsel in clearing up pending matters between Mexican and American interests. (He was quite successful in that field because of his complete familiarity with the problems, languages, and psychology of both peoples.)

During his years in Mexico, among the many problems which faced Mr. Francis was that of labor supply for construction activities in and near Mexico City. This was a great difficulty since labor had not yet been organized in 1910, and Mexican labor instinctively distrusted foreigners. Mr. Francis had to adapt Anglo-Saxon psychology to the Mexican laborer whose life had been spent close to the soil. True to the instincts of a gentleman in a foreign land, he quickly acquired an understanding of the slang and idioms and the customs of the common people.

His time and sympathy were given freely to assist in "ironing out" the problems that appear when labor is in the throes of organization, and the laborers learned to trust him. In the course of time, the governor of the federal district began to inquire about "Howwow," which was as close to Howard as possible in Spanish. Mr. Francis became an authority on the folklore and the songs of the people. His geniality in Spanish and English simultaneously was a source of wonderment to the peon and to the governor alike. One of his pleasures was to write Mexican parodies of American popular songs and play the guitar as an accompaniment. His voice was that of an average engineer, making his parodies the more popular. On two different occasions Mr. Francis saved the lives of Americans who did not know that the Mexican pride is very easy to wound.

Having salvaged a modest competency from these activities, Mr. Francis retired from active affairs and established his home in San Antonio, Tex. During this period he cleared up all pending matters, and thus left no problems for his family to solve after his death.

On March 10, 1926, Mr. Francis was married to Emma Velasco, daughter of Panfilo José Velasco and his wife, Maria, of Mexico, City. The sole survivors of Mr. Francis and his parents are his widow; his daughter, Christina, born on October 3, 1930; and his sister, Mrs. John O. Plank.

Mr. Francis was long associated with the writer, both professionally and socially, and the writer reposed great confidence in him. His brightest accomplishment was in mapping his life and achieving all his major objectives. Few can hope for more or strive for less.

Mr. Francis was elected an Associate Member of the American Society of Civil Engineers on October 1, 1913.

LAWRENCE GRIFFITH, Assoc. M. Am. Soc. C. E.[1]

DIED FEBRUARY 8, 1944

Lawrence Griffith was born in Baltimore, Md., on February 6, 1869, the son of Goldsborough and Eleanor (Michael) Griffith. He was educated in the public schools of Baltimore and was graduated from the Maryland Institute School of Art and Design in Baltimore.

His early engineering experience was on railroad work. From March, 1886, to June, 1890, he served as an apprentice in the machine shops of the Baltimore and Ohio Railroad Company in Baltimore. He then was employed by the Northern Central Railway Company in various capacities: From June, 1890, until December, 1891, he served as rodman on the Baltimore Division; from December, 1891, to January, 1894, he was assistant supervisor, maintenance of way and construction on the Baltimore Division; and, from January, 1894, to October, 1894, he held a similar position with the Canandaigua Division on maintenance of way and surveys for a viaduct over Rock Stream gorge. During the second period he was in charge of (1) the construction of a 104-lever mechanical interlocking machine at the junction of the Baltimore and Potomac Railroad and the Northern Central Railway; (2) changes to bridges at Charles Street, Maryland Avenue, and Lombard Street in Baltimore; and (3) surveys for changes of part of the line, reconstruction of No. 3 yard, and shops at Canton, N. Y.

In October, 1894, Mr. Griffith was placed in charge of surveys for change of line of the Sunbury Division, Philadelphia and Erie Railroad Company. In January, 1895, he was employed by the New York Division of the Pennsylvania Railroad Company on construction and maintenance of mechanical and electric pneumatic interlocking and block signals. From May, 1899, until 1900 he was supervisor of the Grand Central Station Yard in New York, N. Y., directing construction and maintenance of tracks, signals, and interlocking devices.

During World War I from 1915 to 1918, Mr. Griffith was greatly interested in the U. S. Army. He went to the Officers' Training School at Plattsburg Barracks, N. Y., and was a member of Company K, First Provisional Regiment. He was in Plattsburg from September 8 until October 6, 1915, and was interested in riflery.

Much of Mr. Griffith's engineering career centered around the City of Yonkers, N. Y. He was twice city engineer of Yonkers—from January 1, 1918, to December 31, 1921, and from January 1, 1924, to December 31, 1926. During his first period of service, World War I curtailed actual construction, but he supervised and prepared many studies and plans which were later used by the city. Among these were zoning maps (the first to be prepared for Yonkers and the second group to be made in New York State) and a new assessment map using the section block system. During his second term as city engineer, Mr. Griffith revamped much of the Yonkers water supply system and planned the Hillview Reservoir to connect with the Ashokan Water Supply of New York. In addition, he planned and built a model firehouse for suburban areas in the Bronxville section, which received much publicity. On February 9, 1934, Mr. Griffith became president of the Yonkers Mortgage Corporation.

---

[1] Memoir prepared by George W. Kittredge, Hon. M. Am. Soc. C. E.

Always a diligent public servant, Mr. Griffith was a member of the Yonkers Waterfront Commission and engineer and consultant to the Westchester County Transit Commission.

Throughout his entire career Mr. Griffith performed his duties well and was held in high regard, respect, and esteem by all with whom he came in contact.

On June 21, 1899, in New York, he was married to Kate H. Belloni. He is survived by his widow; two daughters, Mrs. Louis G. Butts and Mrs. John S. Priest; a sister, Mrs. James Booker Clark; and a brother, Goldsborough S.

Mr. Griffith was elected an Associate Member of the American Society of Civil Engineers on May 2, 1900.

JAMES RAYMOND HEAD, Assoc. M. Am. Soc. C. E.[1]

DIED JULY 19, 1943

James Raymond Head, the son of L. Walter and Edith Eleanor (Webster) Head, was born at Garden Grove, Orange County, Calif. In 1906 and 1907, he attended the University of California at Berkeley, majoring in civil engineering. He was a member of Phi Gamma Delta fraternity.

In 1907 his engineering career began when he was employed by the Union Lumber Company at Fort Bragg, Calif., on railroad surveys. From 1908 to 1911 he served as engineer on the construction of hydroelectric power plants for the Arizona Power Company at Prescott, Ariz. In 1911 and 1912 he was engaged in general engineering work at Los Angeles, Calif. From 1912 to 1918 he was assistant engineer for the Southern Pacific Railroad Company, Bakersfield Division. Deserting engineering temporarily in 1918 and 1919, he farmed near Tulare Lake, California, and at Chico, Calif.

In 1919 he resumed his professional career, being associated with the firm of Polk and Robinson, Civil Engineers, of Chico, as resident engineer on irrigation, reclamation, and general construction until 1928. During this time, in 1924, he was resident engineer on surveys and investigations for a report on the watershed and storage reservoirs of the Santa Maria Valley in California. In 1929 he was appointed city engineer of the City of Chico. In December, 1929, he became sales engineer with the California Corrugated Culvert Company of Berkeley, Calif., for the northern district of California, remaining in this position until his death. Since the territory of the district included all of northern California, he dealt with city, county, and state officials, the personnel of irrigation, drainage, and reclamation districts, and construction men of all types.

---

[1] Memoir prepared by a Committee of the Sacramento Section consisting of Martin Collins Polk, M. Am. Soc. C. E., Chairman, and Harold Fred Percival and Frederick T. Robson, Assoc. Members, Am. Soc. C. E.

Mr. Head's exceptionally fine personality, honesty, and technical knowledge made him very valuable to his employers. He had a host of friends.

On November 29, 1912, in Bakersfield, Calif., he was married to Rhoda H. Nilsson. His widow and two daughters, Barbara Louise and Marie, survive him.

Mr. Head was a member of Chico Lodge No. 111, F. and A. M., and of the Scottish Rite bodies.

Mr. Head was elected an Associate Member of the American Society of Civil Engineers on February 23, 1932.

WILLIAM JOHNSTON HENDERSON, Assoc. M. Am. Soc. C. E.[1]

Died May 10, 1945

William Johnston Henderson, the son of Edgar Clark Henderson and Adelyia Young (Price) Henderson, was born at Glen Gardner, N. J., on October 31, 1899.

He received the degree of Bachelor of Science in Civil Engineering from Lafayette College at Easton, Pa., in 1922 and the degree of Civil Engineer in 1926. After his graduation, Mr. Henderson spent three years with the Bethlehem Steel Company in the design and fabrication departments. His work consisted of detailing structural steel, of directing the assembly and finishing of structural members and, finally, of estimating and designing. In September, 1925, he became an instructor in structural engineering at Purdue University in Lafayette, Ind. Later he was promoted, successively, to assistant professor and associate professor.

During his teaching days at Purdue University, Professor Henderson progressed in his profession by contacts with various structural firms and engineers. He checked the steel and reinforced concrete design of a large power plant in Cleveland, Ohio, designed several steel and reinforced concrete bridges for the Indiana State Highway Commission, and prepared both the steel and reinforced concrete designs for several of the buildings on the campus. Walter Scholer, the architect for Purdue University, stated that he depended a great deal upon Professor Henderson for the design of the structural parts of several of the university buildings.

Professor Henderson was an excellent teacher—his work was well organized and clearly presented. He believed that the student should be guided by the instructor but should do his own thinking. He maintained high standards and made the students work. They liked this attitude and no complaints were ever heard. With an even temper and without incurring resentment, he pointed out students' faults. The balanced combination of practicality and systematic presentation of theory which he brought into the classroom was valued highly by his students and colleagues. In undertaking any task, either special or routine, he could be depended upon to do a thorough, workmanlike job. Because of his accuracy and reliability, Professor Henderson was given many extra assignments.

---

[1] Memoir prepared by C. A. Ellis and R. B. Wiley, Members, Am. Soc. C. E., and P. E. Soneson, Assoc. M. Am. Soc. C. E.

Outside of the classroom he was the friend of every one, faculty and students alike. As a member and past-president of the Faculty Bowling Club, his unruffled, genial manner and cordial companionship, win or lose, endeared him to all. He was a member of Alpha Chi Rho fraternity, Chi Epsilon, and the American Concrete Institute.

Professor Henderson was married to Ruth Elizabeth Banghart of Glen Gardner on October 4, 1924. He is survived by his widow, his mother, and a brother, Abram B. Henderson.

Professor Henderson was elected an Associate Member of the American Society of Civil Engineers on August 29, 1927.

MAXWELL HENRY, Assoc. M. Am. Soc. C. E.[1]

DIED APRIL 7, 1944

Maxwell Henry was born in New York, N. Y., on December 26, 1897, the son of Simon Henry and Maria Johanna (Meiers) Henry.

His early education was acquired in the public elementary schools and Townsend Harris High School of New York City.

Even as a young man Mr. Henry disclosed those traits and characteristics which ultimately gave him a brilliant career in engineering and teaching. Early evidence of a mechanical bent and desire for information and perfection and his aptitudes in engineering fields led him in his youth to become a skilled craftsman in the electrical field. In 1918, at the age of twenty one, he was one of the few who succeeded in obtaining a license as a master electrician in New York City. For a time, he was an illumination expert for many theatrical and operatic enterprises. During this same period, Mr. Henry was active in the New York City Federation Settlement, directing boys' activities in mechanical and workshop courses and in the technique of theatrical illumination.

In 1919 Mr. Henry interrupted his engineering studies at the College of the City of New York to become instructor, for the college, in electrical wiring and installation on the Rehabilitation Program for Disabled Veterans of World War I. He was in full charge of that department from 1920 until the end of the program in 1924. Mr. Henry received the degrees of Bachelor of

---

[1] Memoir prepared by Sidney L. Cahn, New York, N. Y.

Science and Civil Engineer from the College of the City of New York at a late date—1924—because of the interruption occasioned by his work for the disabled war veterans. He was then invited to, and did join, the college's staff as instructor of engineering in the School of Technology. In 1937 he was promoted to associate professor of Electrical Engineering.

While with the School of Technology, Mr. Henry designed and developed the laboratories and courses in the civil, electrical, and mechanical engineering departments. Because of his varied and expert abilities and talents, he played a most important part in developing and supervising the power and communication laboratories of the electrical engineering department and of the materials testing laboratories of the civil engineering department. He was almost exclusively responsible for all the course work in electrical measurements and illumination. In the field of electrical engineering he became a recognized expert.

In addition to his regular college duties, Professor Henry was called upon, throughout the years, to serve on practically every committee concerned with the buildings and physical improvements of the colleges everywhere in New York City—particularly those of Queens and Hunter colleges. His work in this field, building projects and directing mechanical and electrical improvements for all the colleges of the City of New York, was perhaps one of his greatest contributions to the Board of Higher Education.

In addition to his membership in the Society, Professor Henry was active professionally as a member of the American Institute of Electrical Engineers. He was licensed as a professional engineer in New York State and was engineering consultant to several industrial firms and to the Civil Service Commission of the City of New York. For the last several years he acted as expert examiner for the Civil Service Commission.

As the School of Technology of the College of the City of New York expanded, Professor Henry limited his teaching to the electrical engineering department. For many years he was executive officer of this department. It is doubtful whether the people of the City and State of New York have ever seen a more energetic and capable public servant. No work was too small or menial for Professor Henry, none too large or exacting. His able hand was visible in the new projects for all the colleges everywhere in New York City.

In these colleges, as elsewhere, there were few people, if any, who had not at one time or another sought and obtained Professor Henry's opinion or advice or in some way leaned upon him. During his long connection with the college, he rejected many highly remunerative offers to enter the industrial world, for his heart was in teaching "his boys." His door was always open and all who have passed through his classrooms have known him as a brilliant and effective teacher and adviser and as a kindly and considerate guide. His ability to impart his vast fund of knowledge to others and his patience and tact with his students and the younger men in the departments endeared him in the hearts and minds of his friends and associates throughout the twenty-five years of his devoted service to the College of the City of New York.

Professor Henry's intense activities in college matters during all times of the day, night, summer, and winter were beyond human endurance. He died in the service of the College of the City of New York at the age of forty six, an irreplaceable loss to the people of the City of New York.

He is survived by his widow, Pauline Lichtenstein Henry, D.D.S., to whom he was married on December 24, 1924; a son, Paul Maxwell; and a daughter, Carol Zena.

Mr. Henry was elected an Associate Member of the American Society of Civil Engineers on June 27, 1932.

CURT JOSEPH HEYMANN, Assoc. M. Am. Soc. C. E.[1]

DIED MARCH 30, 1944

Curt Joseph Heymann, the son of Joseph and Odile (Cahen) Heymann, was born of Luxemburgian parents in Aachen, Germany, on October 10, 1910. He attended the Aachen Gymnasium School and the Technische Hochschule Zu Aachen, from which he was graduated with the degree of Bachelor of Science in 1934.

During the years he studied for his degree, Mr. Heymann, by coaching students in Greek, Latin, and mathematics, earned his university fees. After his graduation in June, 1934, and until his departure for South Africa in October, 1936, he was associated with an engineering firm in Paris, France. Arriving in South Africa on October 31, 1936, he proceeded to Johannesburg, Union of South Africa, where he was employed by Spotkin and Newfield, designing reinforced concrete structures.

In March, 1937, he joined the Reinforcing Steel Company, of Johannesburg; and, after a month with this firm, he was transferred to the Durban, Natal, branch, as a structural engineer—estimating, designing, detailing, and supervising the construction of reinforced concrete structures, having full charge and reporting to the manager. During the three and one-half years he was associated with this firm—the boom period of building in Durban—he was responsible for the structural design and the supervision of the erection of many of the fine modern buildings in Durban.

From July to September, 1940, Mr. Heymann was associated with Messrs. Stott, Sullivan and Barbour, surveyors and architects of Durban, as assistant land surveyor. In September, 1940, he joined the Durban Corporation as an engineering assistant, and in this capacity he was engaged on a water system planned by the Durban Corporation. This project includes a gravity dam (storage capacity, 5,000,000,000 gal) with flood diversion control works and an aqueduct 27.7 miles long, consisting of 48-in. reinforced concrete pipe and 42-in. and 36-in. steel pipes in twenty-one tunnels 7.30 miles long. The system, when completed, will provide Durban with an additional 50,000,000 gal of water per day.

---

[1] Memoir prepared by Mrs. Curt Joseph Heymann and H. A. Smith, Assoc. M. Am. Soc. C. E.

Under the direction of the resident engineer, Mr. Heymann completed the design of the flood control gates to the diversion canal. (These gates will divert all silt-laden flood waters from the main storage dam.) In addition, he supervised construction work in the early stages. There are six gates, 18 ft wide by 30 ft long, which will be operated electrically or manually. He also supervised the design of the multiple arch dam, an alternative to the gravity dam, and the design of the 48-in. diameter concrete pipe, a part of the aqueduct.

He was engaged on this work when he was stricken with heart collapse, in December, 1943. Mr. Heymann was confined to his bed, until his death. Thus, the career of a brilliant young man, who showed great promise in the engineering profession of South Africa, was brought to an untimely conclusion. At the end of December, 1943, after residing for the requisite five years in South Africa, he applied for citizenship and was accepted as a naturalized British subject.

On December 26, 1939, Mr. Heymann was married in Dundee, Natal, to Elizabeth Williamson, of the well-known pioneer mining family in that district, who survives him.

Always interested in professional affairs, in June, 1938, he was elected an associate member of the South African Society of Civil Engineers; in February, 1939, an Associate Member of the Institute of Structural Engineers (British); and, in 1942, a member of the British Society of Civil Engineers.

Apart from his great devotion to his work, Mr. Heymann was a brilliant classical scholar and musician.

Mr. Heymann was elected an Associate Member of the American Society of Civil Engineers on October 19, 1942.

JOHN BREWSTER HODGDON, Assoc. M. Am. Soc. C. E.[1]

DIED MARCH 16, 1935

John Brewster Hodgdon, the son of George Washington and Mary Jane (Hobbs) Hodgdon, was born on October 22, 1861, in Rochester, N. H. He received his early education in the Rochester High School, and was graduated with the degree of Bachelor of Science from Dartmouth College at Hanover, N. H., in 1885. As a student at Dartmouth he was a member of Vitruvian (later Beta Theta Pi fraternity), and was active in the outside activities of his class.

A year after graduation he was employed by Knight and Bontecou, of Kansas City, Mo., where he remained only until July, 1886, when he became transitman on location for the Wyandotte and Northwestern Railroad Company in the same city. In 1888 he surveyed and mapped about ten thousand acres of mineral and timber land in Wise County, Virginia; and in 1889 he worked on location for the Kansas City Link Railroad (never built).

---

[1] Memoir prepared from information on file at the Headquarters of the Society.

The next ten years were spent in varying activities. He went to Joplin, Mo., in 1890, supervising construction of the Joplin Electric Railway. The following year he became assistant city engineer in charge of sewer construction. From 1891 to 1892 he worked on the location and the construction of the Southwest Missouri Electric Railway between Webb City and Prosperity, Mo. In January, 1892, he went to Galena, Kans., where he was engaged as a civil engineer on mining and surveying for five years. In 1896 he built the Joplin and Galena Electric Railway, and was chief engineer for the Southwest Missouri Electric Railway Company (later the Southwest Missouri Railroad Company). He then became assistant engineer for the Kansas City, Fort Scott and Memphis Railroad Company, with headquarters in Springfield, Mo., in charge of general inspection and repair work on all bridges from Springfield to Memphis, Tenn., with the exception of the Memphis Bridge. He returned to Joplin in 1899 as chief engineer for the Southwest Missouri Railroad Company.

Mr. Hodgdon became resident engineer for the Kansas City, Memphis and Birmingham Railroad Company, in 1901, with headquarters at Amory, Miss. In 1902 he made land surveys in Mississippi County, Arkansas, and government surveys into the margin of Big Lake (the survey embraced more than 12,000 acres). From 1903 to 1904 he was chief engineer of the Mineral Cities Railway Company, from Joplin to Pittsburg, Kans. From 1904 to 1907 he served as local assistant engineer of the Missouri, Kansas and Texas Railway Company, and as chief engineer of the Southwest Missouri Railroad Company; he also rebuilt tracks at the Galena yards for the Missouri, Kansas and Texas Railway Company.

In 1907 Mr. Hodgdon was appointed city engineer of Joplin, under the councilmanic form of government, and served in that capacity until 1911. In 1914 he became the first commissioner of streets under the commission form of government, resigning in 1918 to superintend the cutting of stone for the Denver Municipal Park Grounds, at Stone City, Colo.

As superintendent of the Baxter Springs, Kans., water works and sewer system from 1920 to 1923, he was instrumental in the installation of the two systems there. Returning to railroad engineering, from 1924 to 1925 he served as engineer for the Kansas, Oklahoma and Gulf Railroad Company.

The City of Joplin reappointed Mr. Hodgdon city engineer in 1930, which position he held until his death. With his wide engineering experience in city, railroad, electric railway, and land surveying; mining engineering; and bridge construction as a background, Mr. Hodgdon specialized during the last several years of his life in municipal street paving. Through experimentation he is responsible for pavement made out of Joplin "chats," a material made from the waste of the lead and zinc mines. This material has proved so satisfactory that a great business has been opened to the mine operators, and these chats have been shipped all over the United States for use in making concrete material.

On August 24, 1887, he was married to Lula I. Akin, of Olathe, Kans., who survives him, together with two sons, Otto Fox Hodgdon and Frank Ralph Hodgdon; a daughter, Ruth May (Mrs. Guy Mills); a brother, Frank Hodgdon; and seven grandchildren.

Mr. Hodgdon was a Thirty-Second Degree Mason and a member of the Scottish Rite and of Joplin Lodge No. 335, A. F. and A. M. He belonged to the Byers Avenue Methodist Church.

Mr. Hodgdon was elected an Associate Member of the American Society of Civil Engineers on April 3, 1907.

JOHN WARDWELL HOWARD, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 25, 1944

John Wardwell Howard, the son of Charles Henry Howard and Susan (Wilson) Howard, was born in Providence, R. I., on March 20, 1879. During his boyhood the family moved to Boston, Mass., and made their home in the Savin Hill section of Dorchester where they lived for a great many years. Mr. Howard attended the Mechanic Arts High School in Boston from which he was graduated in 1899. He then entered the Massachusetts Institute of Technology (M.I.T.), at Boston, being graduated with the degree of Bachelor of Science in Civil Engineering in 1903.

Following his graduation he joined the staff of the Department of Civil and Sanitary Engineering at M.I.T., remaining for forty years. He was an assistant from 1903 to 1905, an instructor from 1905 to 1913, and an assistant professor from 1913 to 1922. He held the rank of associate professor of topographical engineering from 1922 until his death.

Prior to the establishment of the M.I.T. Surveying Camp in Maine in 1912, Professor Howard devoted his summers to outside professional work. His first position was that of rodman with the Pennsylvania Railroad Company from June to September, 1902, between his junior and senior years. During the summer of 1903, he was a member of the staff at the Surveying School held that summer at East Machias, Me. During August and September he served as a field assistant with the Commission on Additional Water Supply for the City of New York (N. Y.).

He worked on the Town Boundary Survey of Massachusetts during the six summers from 1905 to 1910. This project was conducted by the Massachusetts Harbor and Land Commissioners under the supervision of Henry B. Wood,[2] M. Am. Soc. C. E. The work consisted of actually finding all the town boundary corners or angle points and then locating them with reference to the U. S. Coast and Geodetic Survey triangulation system in Massachusetts so that complete town boundary atlases could be prepared. During the summers Professor Howard spent on these surveys, the work principally involved reconnaissance and triangulation in the western part of the state where the terrain was rough and wooded. Considerable skill and ingenuity were required to make satisfactory progress under these conditions. This summer employment gave him an unusually broad and practical experience which was helpful in his teaching.

---

[1] Memoir prepared by John B. Babcock, 3d, M. Am. Soc. C. E.

[2] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 91 (1927), p. 1155.

From January to October, 1912, he was an assistant engineer for the Costa Rica-Panama Boundary Commission. These countries had referred their boundary dispute to the Chief Justice of the United States Supreme Court and a commission of engineers had been appointed to supervise a survey of the territory involved. Frank W. Hodgdon,[3] M. Am. Soc. C. E., one of the engineers of this commission, was chief engineer of the Massachusetts Harbor and Land Commissioners. Since Mr. Hodgdon was familiar with Professor Howard's capable work on the Town Boundary Survey of Massachusetts, he selected Professor Howard to head one of the field parties. There were four field parties, each consisting of an assistant engineer, a transitman, and three rodmen. The group left New York early in January, 1912, for Bocas del Toro, Panama, on the Atlantic Coast. During the actual work in the field, each party had a cook and fifteen to twenty machete men. The first work was a topographical survey of the northerly watershed of the Sixaola River, principally by stadia methods. By June the survey had proceeded so far that the problem of supply became difficult. The parties returned to the coast and were transported by rail across Costa Rica to Puntarenas on the Pacific Coast. With a native Indian village as a base, the survey of the headwaters in the mountains was then completed. This stage occurred during the rainy season when it was possible to work only a few hours each morning. For this reason, and because of unfavorable topographic features, triangulation methods were used for locating this part of the divide. When the survey was finished, the parties returned to New York, arriving in October, 1912. Many hardships were endured in Costa Rica—snakes and malaria causing the chief difficulties. Although a number of the men were stricken with fever, there was but one fatality—a laborer who was bitten by a poisonous snake.

During World War I, in addition to his regular duties, Professor Howard served as an instructor in the U. S. Army School of Military Aeronautics at M.I.T. He was also in charge of a School of Navigation at Portland, Me., for the United States Shipping Board. After the war, he served as coordinator for students attending M.I.T. under the auspices of the Federal Board for Vocational Education, later consolidated in the Veterans' Bureau. His sincere interest in these returning men and his understanding of their problems made his services very valuable.

For nearly thirty years Professor Howard was a member of the staff at Camp Technology, the M.I.T. Summer Surveying Camp on Gardner Lake near East Machias. Although he was on the Costa Rica-Panama Boundary Survey when the camp was opened in 1912, he attended all but two sessions from 1913 to 1942. He was in charge of both administration and instruction from 1935 to 1942, after which the camp was temporarily suspended because of M.I.T.'s adoption of a continuous academic program for the duration of World War II.

---

[3] For memoir, see *Transactions*, Am. Soc. C. E., Vol. LXXXVII (1924), p. 1355.

From 1916 to 1922, students in mining engineering attended the camp for a five-week course in plane and topographic surveying before beginning underground surveying. Professor Howard was in charge of the program for the mining engineering students both at Camp Technology and at mines in Nova Scotia, Vermont, and New Jersey.

His influence on the students who attended the surveying camp was marked. He was recognized by them not only as an able teacher of surveying practice but as one who was always ready to cooperate with them in their activities. He was a sincere friend with whom they could discuss their personal problems. Professor Howard once said,

> "Aside from the many advantages of teaching practical surveying at the Camp during the summer, I have always considered the intimate contact between the staff and students to be of inestimable value to both. We know our men."

How well this ideal was realized is indicated by a quotation from the *Benchmark,* the annual publication by the camp students, in which it was stated,

> "It is an excellent place for work and play, and it offers to us what other courses do not:—the breaking down of the barrier between students and instructor."

In addition to teaching astronomy, geodesy, and plane and topographic surveying, Professor Howard was interested in aerial surveying and photogrammetry and acted as consultant to Army officers interested in this field.

Besides the Society, he belonged to the Boston Society of Civil Engineers, Society for the Promotion of Engineering Education, American Society of Photogrammetry, American Geophysical Union, American Congress on Surveying and Mapping, and Lambda Chi Alpha fraternity. He was a member of the Society's Surveying and Mapping Division and served on its Committee on Definition of Surveying Terms. He was at one time president of the Mechanic Arts High School Alumni Association.

In addition to his professional accomplishments, he was a man who was loved by all who knew him. He was ever ready to sacrifice his personal interest to help a student or a fellow staff member. His office door stood open to all, and within awaited a cordial and warm greeting.

On August 29, 1934, he was married to Alice Elizabeth Welch of Dedham, Mass. He is survived by his widow and by two sisters, Katherine and Mabel Howard.

Professor Howard was elected an Associate Member of the American Society of Civil Engineers on March 4, 1913.

HOWARD CHAPIN IVES, Assoc. M. Am. Soc. C. E.[1]

DIED OCTOBER 6, 1944

Howard Chapin Ives, the son of Howard C. and Julia (Dunham) Ives, was born on March 20, 1878, at Cheshire, Conn. He was graduated from the Sheffield Scientific School, Yale University, at New Haven, Conn., in 1898. He received the degree of Civil Engineer in 1900.

After being employed by the Pennsylvania Railroad Company on its lines west of Pittsburgh, Pa., he joined the staff of the Worcester Polytechnic Institute (W.P.I.) in Worcester, Mass., in 1900 as an instructor in civil engineering. Three years later he went to the University of Pennsylvania in Philadelphia as assistant professor of civil engineering, and then returned to W. P. I. in 1906 in a similar capacity. He was promoted to professor of railroad engineering in 1912. He resigned from this position in 1924. In 1902 Professor Ives was an instructor in the first W. P. I. summer surveying camp at Chaffin, Mass., organized by Arthur W. French, M. Am. Soc. C. E., and after 1906 he was in charge of the annual session.

In collaboration with Professor French, he prepared a textbook on "Stereotomy."[2] Later, with H. E. Hilts, Assoc. M. Am. Soc. C. E., he wrote "Problems in Surveying, Railroad Surveying and Geodesy."[3] He also revised and edited "Field Engineering"[4] by William H. Searles,[5] M. Am. Soc. C. E., and compiled a surveying manual[6] and several books of mathematical and surveyors' tables. With H. R. Saunders he published a textbook on "Map Drafting and Lettering."[7]

In 1908 he was married to Mary Belle Young of Hartford, Conn. Professor Ives is survived by his widow and a brother, Harvey Ives.

After resigning from the faculty of Worcester Polytechnic Institute, Professor Ives moved to California where for a time he was employed in the office of the city engineer of Los Angeles, Calif. He subsequently resided in Laguna Beach, Calif., occupied with revisions of his books. He returned to Waterbury, Conn., in June, 1944.

Professor Ives was a member of the Society for the Promotion of Engineering Education, the National Institute of Social Sciences, and Sigma Xi. He was a Mason and a member of the Independent Order of Odd Fellows.

Professor Ives was elected a Junior of the American Society of Civil Engineers on December 3, 1901, and an Associate Member on April 5, 1910.

EDWARD RESOLVED MACK, Assoc. M. Am. Soc. C. E.[1]

Died March 21, 1944

Edward Resolved Mack was born in Hardwick, Vt., on November 19, 1876, the son of Henry Resolved and Lois (Williams) Mack. He received his preparatory schooling at Hardwick Academy, and was graduated in 1898 from the University of Vermont at Burlington, with the degree of Bachelor of Science in Mechanical Engineering.

Following his graduation, Mr. Mack was employed for a year as draftsman by the Cramp Shipbuilding Company of Philadelphia, Pa. In August, 1899, he entered the Transport Service of the U. S. Quartermaster Department where he remained until May, 1901. During this period he was a member of the engineering staff of the U. S. Army Transport *Thomas,* plying between San Francisco, Calif., and the Philippine Islands. In 1902 he was employed as draftsman by Moran Brothers Shipbuilding Company in Seattle, Wash., on the construction of the battleship, *U. S. S. Nebraska.*

Returning east in July, 1902, Mr. Mack had short engagements as draftsman with the Woodbury Granite Company of Hardwick, and with the New York Shipbuilding Company of Camden, N. J. On January 1, 1904, he entered the employ of the Water Department of the City of Wilmington, Del., in charge of surveys for a water filtration plant and a concrete conduit line. When this work was completed in September, 1906, he was appointed park engineer and secretary of the Board of Park Commissioners of the City of Wilmington. He continued in this position until his death.

Edward Mack brought to his work a great love of nature and its beauties, together with a consuming interest in the young and underprivileged. The coordination of the esthetic and the recreational phases of park and playground systems with the development and benefit of the youth of the city was his high ideal and one he persistently and steadfastly followed. During the thirty-eight years that Mr. Mack served as park engineer for the City of Wilmington, the park and playground systems were greatly enlarged and modernized by the addition of swimming pools, playgrounds, athletic fields, trails, and picnic sites.

He made several trips abroad and had visited and studied many of the park systems of Europe, Canada, and the United States.

Mr. Mack was the first scoutmaster in Delaware, organizing the initial Boy Scout troop in 1910. He retained his interest in scouting until his death. In 1940 he was awarded the Silver Beaver "for outstanding service to boyhood" by the Del-Mar-Va Council, Boy Scouts of America. He was a charter member of the Social Service Club and a member of the Rotary Club and Grace Methodist Church. He also belonged to the American Association of Park Executives and the Regional Planning Commission of New Castle County. From 1928 to 1932, he served on the Technical Advisory

---

[1] Memoir prepared by W. W. Mack, Chf. Engr., State Highway Dept., Dover, Del.

Committee of the Regional Planning Federation of the Philadelphia Tri-State District.

On September 2, 1914, Mr. Mack was married to Ruth Kellogg of Columbus, Ohio, who survives him.

Mr. Mack was elected an Associate Member of the American Society of Civil Engineers on June 7, 1905.

JAMES ALEXANDER McFADDEN, Assoc. M. Am. Soc. C. E.[1]

DIED OCTOBER 22, 1944

James Alexander McFadden, the son of Dr. John James and Elizabeth (Williams) McFadden, was born in Brandon, Man., Canada, on November 5, 1900. He was descended from a family who for generations had lived in Canada. His grandfather, Moses McFadden, was one of the Dominion land surveyors and engineers who laid out the roads of Manitoba.

After a preparatory education in the schools of his home town, he entered the University of Manitoba at Winnipeg, Man., Canada, where he completed two years of liberal arts followed by a four-year course in civil engineering, being graduated in 1925 with the degree of Bachelor of Science in Civil Engineering. When the university reopened in the autumn of 1925, he became instructor in civil engineering, and, in addition to teaching, he did postgraduate work in hydraulics.

Eager to be "in the field," Mr. McFadden left the university at the end of the 1926 semester and obtained employment in Chicago, Ill., with Consoer, Older, and Quinlan, municipal engineering consultants. He was with this firm for nearly four years, engaged principally on paving, sewer, and water-main construction projects. Starting as inspector, he advanced from assistant resident engineer to resident engineer, and finally to designer.

In 1929 he went with the Commonwealth Edison Company, where, as structural engineer, he worked for more than two years on designs related to steam power stations. He then was appointed civil engineer for both the United States Forest Service and the National Park Service at Ames, Iowa, on a program of park improvement projects. During this time he designed small dams, bridges, sewers, and water-supply systems. In January, 1936, he transferred to the Public Works Administration in the Des Moines (Iowa) area as assistant resident engineer on sewer and water supply projects.

Mr. McFadden went to Knoxville, Tenn., in December, 1936, to work for the Tennessee Valley Authority (TVA), bringing with him a strong enthusiasm for the kind of engineering that was being undertaken by that organization. As an assistant structural engineer in the Construction Plant Division, he was engaged on many phases of design connected with the construction of TVA dams and power plants, including the Hiwassee Dam cableway and the suspension bridge on the Watts Bar project. In April, 1939, he was promoted to associate structural engineer and was placed in charge of a design squad. In July, 1941, Mr. McFadden was transferred to the Civil Design Division, which was expanding rapidly because of increasing war activities. Here he continued as a squad supervisor. When, in the summer of 1942, the position of administrative assistant to the head of the Civil Design Division became vacant, Mr. McFadden was the logical choice because he already demonstrated a marked ability to handle personnel and production work for a large group of engineers. In line with his new responsibilities, he was promoted to civil engineer, and, from the time he assumed his new d until his forced retirement shortly before his death, he was deeply concerned with the TVA emergency program and its continuously changing problems involving procurement and high-pressure production schedules. All this he managed in his efficient manner, and his unfailing sense of humor helped enormously to boost the efforts and morale of his co-workers. It was a vexatious problem indeed that could take the ready smile from his face or eliminate the quizzical sparkle from his eye. He had a habit of standing at the door of his office in the morning or just after lunch, cigarette in the hand raised against the door frame. Just to see him standing there relaxed, with his pleasant greeting ready for everybody, was a good beginning for the day. Any one approaching him, whether for information or to pass a moment in discussion, was struck by his essential gentility and kindness. At the same time, his almost-red hair indicated determination and mental courage.

---

[1] Memoir prepared by P. J. Gordon, Associate Structural Engr., TVA, Knoxville, Tenn., and B. H. Arneberg and Adolf A. Meyer, Members, Am. Soc. C. E.

Mr. McFadden was married on June 30, 1928, to Ingrid Haerem. He is survived by his widow; three children, John Alf, Barbara, and Elizabeth Ann McFadden; his mother, Mrs. J. J. McFadden; two sisters, Eleanor Gertrude McFadden and Margaret Elizabeth (Mrs. J. H. Grahame); and two brothers, Hamilton Saunders McFadden and Jack N. McFadden.

The last years of Mr. McFadden's life were spent in Norris, Tenn., where he took an active part in community affairs. He was a member of the board for the Norris Cooperative and a member and treasurer of the Norris Forum Committee, in which capacity he aided greatly in arousing public interest in postwar problems. For some time he also served on the executive committee of the Norris Council, Boy Scouts of America. He held the license of professional engineer in the State of Iowa.

Mr. McFadden was elected an Associate Member of the American Society of Civil Engineers on July 11, 1938.

JOHN FRANCIS MINIHAN, Assoc. M. Am. Soc. C. E.[1]

Died August 14, 1944

John Francis Minihan, the son of Daniel and Margaret (Connolly) Minihan, was born in San Francisco, Calif., on May 8, 1896. He attended Mission

---

[1] Memoir prepared by M. B. McGowan, Jr., Assoc. M. Am. Soc. C. E.

High School in San Francisco and then studied civil engineering at the University of California at Berkeley and was graduated in May, 1918, with the degree of Bachelor of Science in Civil Engineering.

He began his professional career on the design and detail of steel structures for the Judson-Pacific Company, under E. O. Burgess, and then proceeded to other professional assignments as follows:

1920–1922—Engineer of design and detail of high-tension electric transmission towers for the Pacific Coast Steel Company of San Francisco.

1922–1927—Estimator and office engineer on building construction of all types for Cahill Brothers, Inc.

1927–1932—Estimator, office engineer, and assistant superintendent on building construction for J. A. Bryant, Inc.

1932–1937—Estimator and office engineer on bridges, pile foundations, wharves, and cofferdam construction for M. B. McGowan, Inc.

1937–1939—Chief estimator for the Golden Gate International Exposition.

1939–1940—Vice-president of the Lane-Minihan Construction Company.

1941–1942—Office engineer in charge of all field operations for construction of piers and buildings in ammunition area at the Mare Island Navy Yard, California, for Cahill-Gerwick Company.

1942–1943—Engineer in charge of estimates, estimates for payment, and plant history of methods on 5,000 prefabricated housing units (Federal Housing Project) at Norfolk, Va., for Barrett and Hilp, Inc.

1943–1944—Chief inspector for the Federal Housing Administration at the $3,000,000 Ridge Point project (2,000 dwelling units including utilities) at Hunters Point, San Francisco.

At the time of his death Mr. Minihan was checking material lists prepared by J. H. Pomeroy for the U. S. Navy, and was considering opening an estimating and quantity survey office to serve the construction industry.

As a specialist in the most difficult quantity survey work and heavy construction pricing, Mr. Minihan had few equals; and his own exhaustive job cost records, from actual experience, could well have made him famous had he chosen to publish rather than to apply them. He held great hopes for the future of prefabrication. Complete works on prefabrication history and construction methods were in his extensive historical and engineering library. He was identified during his career with some of the great engineering achievements of all time, such as the San Francisco-Oakland Bay Bridge, the Golden Gate Bridge, and the Golden Gate International Exposition. He left a record that few men in his field have been able to attain.

John Francis Minihan was well known to, and beloved by, many members of engineering and construction firms in the San Francisco Bay area. His cheery disposition and his keen wit made him one of the most intelligent and lovable characters in the California construction industry.

On May 7, 1932, in San Francisco, he was married to Anne Cooney. Mr. Minihan is survived by his widow and two sisters, Agnes (Mrs. C. A. Young, Jr.) and Helen (Mrs. J. P. Cassidy).

His death was deeply felt by the many engineers and contractors with whom he had so long been friendly, and all of them will join in wishing him Godspeed to the Valhalla of good engineers. His wit and his charm will live long in the hearts of his many friends.

Mr. Minihan was elected an Associate Member of the American Society of Civil Engineers on August 29, 1927.

WILLIAM JOHNSTON MITCHELL, Assoc. M. Am. Soc. C. E.[1]

Died May 19, 1943

William Johnston Mitchell, the son of David and Mary (Johnston) Mitchell, was born at New Bedford, Mass., on November 2, 1890. He received his preliminary education in Fairhaven High School, Fairhaven, Mass. In 1913 he was graduated from the University of Maine at Orono with the degree of Bachelor of Science in Civil Engineering. When at college, he was elected to the honorary engineering society, Tau Beta Pi.

After graduation, Mr. Mitchell obtained a position with the American Bridge Company as structural detailer at the Brooklyn (N. Y.) plant. In February, 1915, he was detailer and designer of reinforced concrete structures for the Trussed Concrete Steel Company of New York, N. Y. Six months later he was employed by Felnheimer and Long, Architects of New York City, to assist in the design of railroad structures.

In October, 1915, Mr. Mitchell became a checker of structural steel details with Gunvald Aus Company of New York, continuing until June, 1916. At this time he transferred to the Leetsdale (Pa.) plant of the Riter-Conley Manufacturing Company of Pittsburgh, Pa., where he remained until he enrolled for service in World War I.

Mr. Mitchell enlisted in the U. S. Army on May 17, 1918, at Washington, D. C., as a private in the 29th Engineers. After a few months of training, he sailed from Hoboken N. J., on July 8, 1918, on the steamer *Toba*. On July 19 he arrived in France, landing at Brest, then being sent to Fort de Saint Mange, where he served as instructor in flash ranging until December 26. He sailed from Saint-Nazaire, France, on February 28, 1919, and arrived at Newport News, Va., on March 11, 1919. He was discharged from Camp Dix (New Jersey) on March 24, 1919.

Mr. Mitchell resumed his civilian life as designer and estimator for the Berlin Construction Company of Berlin, Conn. In September, 1922, he accepted a position as structural designer with the Mining Department of the Bethlehem Steel Corporation in Bethlehem, Pa., specializing in the design of wood, steel, and concrete structures for the mines and quarries of the Bethlehem Steel Corporation. In February, 1932, drastic curtailment of work caused by the economic depression gave Mr. Mitchell an opportunity to retire and supervise the real estate properties his father had left when he died. At this time Mr. Mitchell (who never was married) lived with his mother. In 1934 they decided to spend a winter in Florida, liking it so well that from then on they spent their summers in Fairhaven and their winters in Saint Petersburg, Fla.

---

[1] Memoir prepared by E. C. Waite, Assoc. M. Am. Soc. C. E.

The outbreak of World War II, with the resultant vast industrial program, led Mr. Mitchell to decide to help by taking a job at the Bushnell Lyons Iron Works, at Tampa, Fla. This organization did considerable work on the construction of phosphate plants but finally specialized in landing barges.

Because of the pressure of work Mr. Mitchell did not return to Massachusetts in 1942 but continued with the Iron Works until he became ill in February, 1943. He was admitted to the hospital in Tampa and was later transferred to the Bay Pines (Fla.) Hospital, where he died on May 19, 1943. A military funeral was held on May 20, and he was buried in the Bay Pines Cemetery.

An active member of the American Legion, Mr. Mitchell also belonged to La Société des 40 Hommes et 8 Chevaux.

Mr. Mitchell was elected an Associate Member of the American Society of Civil Engineers on May 25, 1931.

RUSSELL MELVIN OBERT, Assoc. M. Am. Soc. C. E.[1]

Died June 5, 1943

Russell Melvin Obert was born at Columbus, Ohio, on November 5, 1901, the son of William and Emma (Reichert) Obert. His maternal grandfather and paternal grandparents were natives of Germany. Educated in the public schools of Columbus, he entered Ohio State University, also in Columbus, in September, 1920, and was graduated with the degree of Bachelor of Civil Engineering in June, 1924.

From June, 1924, to August, 1925, he was engaged as transitman with the Bureau of Water Works Extension of the City of Columbus, in connection with the construction of the O'Shaughnessy Dam. From August, 1925, to October, 1926, he was with the Pure Oil Company, as draftsman and, for the latter part of the engagement, as designer in charge of concrete and structural work at Chicago, Ill. From November, 1926, to December, 1927, he was employed by the International Derrick and Equipment Company of Columbus as a structural draftsman, superintending construction of shop building extensions and serving as engineering representative on office building construction.

In January, 1928, he became an assistant engineer for The Columbia Engineering Corporation at Columbus and until his death served this organization in various capacities, being principally engaged in valuation and appraisal work for various companies held by the corporation in Ohio, Pennsylvania, West Virginia, and Kentucky. A fitting eulogy to Mr. Obert was expressed by an associate at the time of Mr. Obert's death in the *Broadcaster,* a company publication from which the following is taken:

---

[1] Memoir prepared by John A. Rousculp, Assoc. M. Am. Soc. C. E.

> "Russell (Russ) Obert passed from our midst on June 5th, but is not forgotten. Russ was the victim of a heat stroke, while working in his victory garden, and never regained consciousness. With his untimely death there comes a distinct sense of loss to his family, community, and our company, because he was always eager to do more than his part, going out of his way, voluntarily, to do little favors for others. A hard-working individual, who was not satisfied with anything but his best performance on any assignment.
>
> "Russ was employed by The Columbia Engineering Corporation on January 16, 1928, as an Assistant Engineer. Later he served as Senior Engineer in charge of material pricing, inventories and appraisals. Among other activities he was President of the Employees' Credit Union in 1942 and 1943, and also served as a Gasco Club Officer and Merchandise Sales Chairman. He was a member of the Quarterback Club, a Red Bird baseball team booster, and a flower and garden enthusiast."

In 1923 he was married to Lola Mildred O'Brien, of Columbus. He is survived by his widow, his parents, and a brother, Floyd H.

He was a lifelong member of St. Johns Evangelical Church of Columbus.

Mr. Obert was elected a Junior of the American Society of Civil Engineers on April 12, 1926, and an Associate Member on November 26, 1934.

WILLIAM SCHUYLER POST, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 24, 1945

William Schuyler Post was born on August 21, 1871, in Vienna, Austria. He was the son of Gen. Philip Sidney Post and Cornelia (Almira) Post. His father had served with distinction in the Civil War and was, at the time of William Post's birth, United States Consul General in Austria. General Post's tour of duty as Consul ended in 1876, at which time the family returned to the United States and settled in Galesburg, Ill., where young Post spent his boyhood. He attended the public schools and later entered Knox College in Galesburg, being graduated at the age of seventeen. He then spent two years at the Corcoran Scientific School in Washington, D. C., and one year at Johns Hopkins University in Baltimore, Md., studying electrical engineering.

After graduation—during 1889 and 1891 and 1893 and 1897—Mr. Post served as chief of party on topographic surveys for the U. S. Geological Survey. This work included primary triangulation in Wyoming and South Dakota. In 1898 he was topographer for the same department on the exploration of southwestern Alaska. In 1900, after a short period as engineer for the Port

---

[1] Memoir prepared by Harry Day Chapman, Assoc. M. Am. Soc. C. E.

America Railway Company in Puerto Rico, Mr. Post moved to Los Angeles, Calif.

During World War I, Mr. Post served as Major in the 316th Engineers and later on the Regimental Staff.

Although Mr. Post's engineering activities covered a large and varied field, he specialized in hydraulics. He served as chief engineer for the Guyamaca Mutual Water Company on reconstruction, flumes, concrete siphons, and appraisements, and he appeared before the California Railroad Commission on company affairs. He was chief engineer of the Vulcan Light and Water Company and the San Dieguito Mutual Water Company (later combined in the Lake Henshaw System for the supply of water to San Diego, Calif.). He also served as engineer in charge of hydraulic investigations and water installations in Kings County and in Whittier, Calif., under J. B. Lippincott,[2] Hon. M. Am. Soc. C. E.

Mr. Post did much work for the State of California. From 1921 to 1923, as hydraulic engineer, he was one of the three principal assistants to the deputy state engineer on water resources investigation, in charge of reservoir studies and dam estimates. From 1927 to 1929, under the same title, he made and was in charge of "The Santa Ana River Investigation" and was the author of a report on the flood control and conservation of water of the Santa Ana River.[3]

During 1929 and 1930 Mr. Post was resident engineer in charge of the construction of the Hogan Dam, built on the Calaveras River for flood control purposes by Stockton, Calif. He made reconnaissance and hydrographic surveys for this project; and, in association with Frederick H. Tibbetts,[4] M. Am. Soc. C. E., consultant of San Francisco, Calif., was joint designer of the dam, constructed at a cost of $1,000,000.

In 1931 Mr. Post, having passed the civil service examination for senior civil engineer (hydraulics) as No. 2 eligible man, was appointed director of irrigation, U. S. Indian Service, in charge of twenty-six projects. Later he became supervising engineer at large. He left the U. S. Indian Service in 1934 and entered the U. S. Park Service, with headquarters at Death Valley, Calif.

In 1935 Mr. Post was employed by the Public Works Administration. He acted as resident engineer inspector during the raising of the Hetch Hetchy Dam for the City of San Francisco and later on the water supply project at Tilden Park, for the cities of Oakland and Berkeley, Calif. In 1940 he again entered federal service as hydraulic engineer, U. S. Engineer Department, in Los Angeles, remaining in that position until he was retired. After his retirement, Mr. Post was employed by the Pacific Naval Air Bases—a combination of contractors for constructing and handling air bases on the Pacific coast—at Ventura, Calif. When he died, he was in charge of the library for that outfit.

[3] *Bulletin No. 19*, Div. of Eng. and Irrig., State of California, Sacramento, 1929.

[4] For memoir, see *Transactions*, Am. Soc. C. E., Vol. 105 (1940), p. 1924.

William Schuyler Post was a great reader and student. He knew his work from beginning to end. Since he had a wonderful memory and a great knowledge and understanding of general and current affairs, he was interested in public matters and did not hesitate to transmit his views and comments to his Senator or Representative or to county and town officials. His was the courtesy of the old school—with the "saving grace of humor." He was a fine "Chief"—capable, kind, and considerate of his subordinates; a fine husband and father; and a good citizen and a loyal friend.

In 1900, in Los Angeles, Mr. Post was married to Estelle C. Johnson, whom he had met when he lived at Galesburg. He is survived by his widow and two children, William Schuyler Post, Jr. (Commander, U. S. Navy Submarine Service), and Carolyn (Mrs. Evan E. Fickling).

He was a member of the Los Angeles Section of the Society for many years before his death.

Mr. Post was elected an Associate Member of the American Society of Civil Engineers on May 1, 1901.

MARION deKALB SMITH, JR., Assoc. M. Am. Soc. C. E.[1]

Died January 20, 1944

Marion deKalb Smith, Jr., was born in Chestertown, Kent County, Md., on July 30, 1879, the son of Marion deKalb Smith and Addie (Burchinal) Smith. His primary education was received in the public schools of Chestertown, and, after being graduated from the local public school, he entered Washington College in Chestertown. He was graduated from this college with the degree of Bachelor of Arts in 1898, after which he entered Cornell University at Ithaca, N. Y., being graduated with the degree of Civil Engineer in 1901.

Immediately after graduation from Cornell, he took a position with the Pennsylvania Railroad Company, and was with this railroad until 1924. Following the death of Mr. Smith's parents, he resigned from the Pennsylvania Railroad Company. Because there were only two surviving members of Mr. Smith's family—himself and his sister, neither of whom ever married—it seemed advisable for him to return to the old family homestead in Chestertown. Thus, in 1924, Mr. Smith began to participate actively in the affairs not only of the City of Chestertown, but also of Kent County. There was no necessary public or civic enterprise of any size or value to the community which was not willingly undertaken by him without compensation.

The Maryland State Roads Commission called upon Mr. Smith for expert advice on the future development of roads not only in his own county, but throughout the state, and several schemes for the development of through highways were presented by Mr. Smith during this period. The citizens of Chestertown sought his advice and counsel in organizing and building the Chester

---

[1] Memoir prepared by Henry Powell Hopkins, Architect, Baltimore, Md.

River Yacht and Country Club. He was a charter member of this organization and remained, until his death, a close adviser and participator in its every activity.

Long a champion of school improvement in Kent County, Mr. Smith gave unstintingly of his personal knowledge and his time to improve the school system not only in the City of Chestertown, but also in Kent County, and it was unfortunate that he did not live sufficiently long to see his efforts bear fruit. As an active member of the Kent County Historical Society, he was instrumental in having a monument erected on the public square in Chestertown to commemorate the three hundredth anniversary of Kent County.

Mr. Smith was one of the founders of the Rotary Club of Chestertown and until his death held a 100% record for attendance as a member of this organization. He attended all the district conferences and was sent as a delegate from his club to the Rotary International in Europe in 1927.

Washington College, his early alma mater, Cornell University, his second alma mater, and last, his home community, the City of Chestertown in Kent County, lost, upon the death of Mr. Smith, a valuable public-spirited citizen.

Mr. Smith was elected a Junior of the American Society of Civil Engineers on October 1, 1901, and an Associate Member on September 5, 1911.

GEORGE PHILIP ALEXANDER STAPE, Assoc. M. Am. Soc. C. E.[1]

DIED DECEMBER 3, 1943

George Philip Alexander Stape was born in Rochester, N. Y., on August 2, 1887, the son of Amelia (Nagle) and Philip Stape.

Mr. Stape was graduated from East High School in Rochester and in 1909 from the Rochester Mechanics Institute. He then attended the University of Michigan in Ann Arbor and was graduated with the degree of Bachelor of Science in Civil Engineering in 1914. In preparatory school and in college, he was interested in all sports, but wrestling, football, and baseball were his favorites. At Michigan, he was class champion in wrestling in his weight class and played baseball and football on class teams. While attending school, he worked summers for the construction department of the Rochester Gas and Electric Company as a surveyor on the construction of the Central Avenue dam and the rock tunnel through the Genesee River gorge in Rochester.

After graduation, Mr. Stape's early professional work was with the automobile and aircraft industries. From 1914 to 1916, he worked as maintenance engineer on factory maintenance for the Cadillac Motor Car Company in Detroit, Mich. In 1916 and 1917, he was engineer in charge of new buildings, maintenance, and factory equipment for the Saxon Motor Car Corporation in Detroit. From 1917 to 1920, he served as planning engineer on equipment, tools, building construction, and plant maintenance for the Dayton Wright Airplane Company of Dayton, Ohio.

---

[1] Memoir prepared by Harry W. Eustance, M. Am. Soc. C. E.

In 1920 he returned to Rochester, his home town, and entered the employ of the Eastman Kodak Company. He remained with this company for twenty-four years until his death. Most of his work was for the Engineering and Maintenance Department of Kodak Park, designing and supervising the construction of buildings and equipment specially devised for the manufacture of photographic film and paper.

Mr. Stape was an excellent associate and his unassuming manner matched the daily evidence of his quiet competence. He had few intimate friends, but those who had the opportunity to know him well valued his friendship and respected him most highly.

To dwell on Mr. Stape's professional work is to neglect what was, to him, the one important task he must do well. Only those who knew him best were aware of the depth of his devotion and the scope of his constant service to his wife, his mother, and his younger sister.

In 1914 Mr. Stape was married to Mary Bernadette Christner of Rochester. After only one year of normal happily married life, Mrs. Stape contracted tuberculosis and lived for ten years as an invalid. Mr. Stape willingly gave up most outside interests and activities to spend as much time as possible in an attempt to help his wife regain her health. Mr. and Mrs. Stape spent much time in the Adirondack Mountains and in the Finger Lake region of New York State. Mr. Stape willingly suspended his professional career to make all these trips possible.

After the death of his wife in 1924, Mr. Stape lived with his mother, remaining with her until her death in 1940. She also was an invalid for several years and was devotedly cared for by her son who was her constant attendant. After his mother's death, Mr. Stape made his home with his sister, Bertha L. Stape, in Rochester. He was devoted to his family and in turn dearly beloved by them. In addition to his sister, Bertha, Mr. Stape is survived by three other sisters, Helen (Mrs. E. B. Gottschalk), Amelia M. (Mrs. August Heim), and Charlotte (Mrs. E. A. Pappert); and two brothers, Harry J. and Howard A.

Mr. Stape was elected an Associate Member of the American Society of Civil Engineers on April 14, 1919.

CHARLES AUGUST THANHEISER, Assoc. M. Am. Soc. C. E.[1]

DIED FEBRUARY 8, 1944

Charlie Thanheiser, as he was known to all his friends in this section of the United States, was born in Fayetteville, Tex., on November 3, 1881.

---

[1] Memoir prepared by Charles R. Haile and W. W. Washburn, Members, Am. Soc. C. E.

He attended the public schools in Fayette County, and continued his education at the Agricultural and Mechanical College of Texas in College Station, where he was a distinguished student and completed the four-year course in three years. He was graduated in June, 1901, with the degree of Bachelor of Science in Civil Engineering.

Upon graduation from college, Charlie Thanheiser immediately went to work for the Southern Pacific Lines of Texas as rodman, and continued until November, 1912, advancing to instrumentman, locating engineer, roadmaster, resident engineer, and division superintendent. He severed his connection with the Southern Pacific Lines of Texas in November, 1912, to accept a position with the Missouri, Kansas and Texas Railway Company of Texas, and served this company until 1916, as chief engineer, maintenance of way, and division superintendent.

From July, 1916, to October, 1922, he was consulting engineer for the Youngstown Sheet and Tube Company and Brier Hill Steel Company of Youngstown, Ohio. He was consultant on the construction of the large expansion program during World War I for these companies and on the construction of the necessary railroad and dock terminals.

In December, 1922, he organized the Southwestern Construction Company of Houston, Tex., and remained as president and principal owner until his retirement in 1932. This company, under his ownership and management, constructed many of the large buildings in the Gulf Coast area of Texas, some of which are: The Plaza Hotel, the City of Houston Public Library, and St. Paul's Methodist Church, in Houston; and the La Salle Hotel, in Beaumont.

From 1932 until his death, Mr. Thanheiser owned considerable property in Houston and also a Brazos River bottom farm, to which he devoted his time.

In addition to serving his own company, he contributed much to the development of the construction industry in south Texas. For seven terms he was president of the Houston Builders Exchange. Throughout his entire career, Charlie Thanheiser took an active part in civic affairs, serving on many committees of the Houston Chamber of Commerce, and until shortly before his death he was chairman of the athletic committee of the Chamber of Commerce. He loved sports of all kinds and took an active part in the direction of sports programs in southern Texas.

Charlie Thanheiser was known and loved by every man who ever attended Texas Agricultural and Mechanical College. He gave generously and was liberal in any movement that was to the benefit and betterment of the college. He served the Ex-Students Association of the college as state president, and several times was president of the Houston Agricultural and Mechanical Club. For a number of years, Charlie Thanheiser was the representative of the Ex-Students Association on the athletic committee of the Agricultural and Mechanical College of Texas. It was through his advice and counsel that a program was arranged which cleared the athletic plant and stadium of the well-known Texas Aggies of all indebtedness.

He was a member of the Texas Section of the Society, the Houston Club, and the Trinity Episcopal Church. He was a Thirty-Second Degree Mason and a Shriner.

In the death of Charlie Thanheiser, Houston lost one of its most respected engineers and constructers and an active participant in civic affairs.

Mr. Thanheiser was married to Adele Lindemann on January 7, 1920. He is survived by his widow and two sons, Charles A. Thanheiser, Jr. (Second Lieutenant, Coast Artillery, U. S. Army), and Will Hugh Thanheiser (a midshipman at Northwestern University in Evanston, Ill.).

Mr. Thanheiser was elected an Associate Member of the American Society of Civil Engineers on July 10, 1907.

JOSEPH JEANES WALKER, Assoc. M. Am. Soc. C. E.[1]

Died July 26, 1944

Joseph Jeanes Walker was born in New Centerville, near Philadelphia, Pa., on November 4, 1871. He was the son of Joseph Robinson and Ellen Wells Walker. His family was one of the old Quaker families of Pennsylvania, and he was the eighth Joseph Walker, in direct descent, to be born in the home built by his original ancestor, Lewis Walker, on land granted by William Penn.

Mr. Walker attended the Friends' Central School in Philadelphia and Swarthmore College in Swarthmore, Pa., from which he was graduated in 1892 with the degree of Civil Engineer. He belonged to Delta Upsilon fraternity and was elected a member of the honorary scientific society of Sigma Xi.

He began his active engineeering career as a rodman in the engineering corps of the Pennsylvania Railroad Company, under W. L. Ziegler, inspecting masonry and brickwork during the construction of the Broad Street Train Shed. In 1894 he entered the employ of the Shiffler Bridge Company of Pittsburgh, Pa., first as a detail draftsman and later as a designer and estimator. In 1896 he was transferred to the Philadelphia office of the company and placed in charge of designing, estimating, and contracting. In 1897 he was transferred to the New York (N. Y.) office as assistant engineer in charge of designing, estimating, and contracting.

In 1900 he joined the newly formed American Bridge Company (a subsidiary of the United States Steel Corporation) and was assigned to the Structural Engineering Department at the East Berlin (Conn.) office as assistant engineer on cost estimates for mill buildings and on miscellaneous structural work. In 1901 he was transferred to the New York office and placed in charge of cost estimates for all classes of bridge and structural steelwork. Among some of the steel structures for which Mr. Walker supervised the cost estimates were New York subways, New York Terminal of the Pennsylvania Railroad Company, Hudson Terminal Building, Rockefeller Center buildings, Equitable Life Insurance Building, New York Life Insurance Building, Empire State Building, the Trylon and Perisphere of the New York World's Fair, and the Bronx-Whitestone Bridge.

---

[1] Memoir prepared by J. E. Wadsworth, M. Am. Soc. C. E.; Warren D. Benedict, Dobbs Ferry, N. Y.; and Charles W. Geoghegan, Asst. Engr., American Bridge Co., New York, N. Y.

In 1938, upon reaching the retirement age for employees of the United States Steel Corporation, Mr. Walker opened an office in New York City as consulting engineer. He was engaged as a consultant on the 60,000-ton steel contract for the Parkchester Apartments, built by the Metropolitan Life Insurance Company in the Borough of the Bronx in New York City.

Mr. Walker was a resident of Dobbs Ferry, N. Y., and always took an active interest in civic affairs. In 1905 he was elected president of the Dobbs Ferry Chamber of Commerce. From 1907 to 1933 he was a member of the Board of Trustees of the village. In 1933 he was elected Mayor of Dobbs Ferry. Every two years since 1933 he was reelected and, when he died, he was serving his sixth term. For the last two terms he had no opposition for election.

His engineering experience was a great asset in his work as Trustee and Mayor of the Village of Dobbs Ferry. In 1938 he designed and supervised the construction of a retaining wall, costing $24,000, along the tracks of the New York Central Railroad in Dobbs Ferry. He designed and secured the approval of two Works Project Administration (W.P.A.) projects for paving and street work—one costing $40,000 and the other, $10,000. In 1941 he designed and supervised the construction of a $20,000 sewer system for the village.

Mr. Walker was a member of the American Bridge Engineering Club of New York (one of the organizers), the American Iron and Steel Institute, the Hendrik Hudson Boy Scout Council (past-president), the New York State Conference of Mayors, and the Westchester County Village Officer's Association (former president). With the entrance of the United States into World War II, Mr. Walker was appointed deputy director of civilian protection in Westchester County. He immediately organized an active defense organization in his village and worked tirelessly.

Mr. Walker was well born; and, from his Quaker ancestors, he inherited honesty, integrity, and loyalty. He did not hide these qualities but developed them into a well-rounded Christian character. He had many friends to whom he was always loyal. To him a promise meant that it must be fulfilled.

On October 6, 1904, in Dobbs Ferry, he was married to Florence Amy Davidson. He is survived by his widow; a son, Joseph P. Walker (Lieutenant, U. S. Navy); a daughter, Elizabeth (Mrs. Alonzo Milton George); and a brother, Charles W. Walker.

Mr. Walker was elected an Associate Member of the American Society of Civil Engineers on November 5, 1902.

HERBERT KIRKMAN WARD, Assoc. M. Am. Soc. C. E.[1]

DIED MAY 28, 1942

Herbert Kirkman Ward was born in San Diego, Calif., on September 22, 1882, the son of Sampson Lett and Ella (Kirkman) Ward. He attended the public schools of San Diego and completed an engineering course in the International Correspondence School.

Mr. Ward began his professional career in 1901 as rodman and chainman for the San Diego and Eastern Railway. From September, 1902, to November, 1903, he was employed as rodman on the subdivision of government lands. From March, 1904, to February, 1905, he was rodman and timekeeper for the California Mountain Water Company, which supplied San Diego and surrounding areas; and, from June, 1905, to June, 1906, he was resident engineer in charge of construction of five miles of wood-stave pipe and erection of a filter plant and reinforced concrete water tower at the Chollas Heights Reservoir and of a pipe line from the reservoir to the City of San Diego.

From July, 1906, to February, 1908, Mr. Ward was engaged in private practice with his father in San Diego County on land subdivision and resurveys. From March to September, 1908, he was levelman for the San Diego and Arizona Railway Company. He was employed by the San Diego County Highway Commission from October, 1908, to September, 1909, successively as transitman and assistant engineer on highway location.

In October, 1909, Mr. Ward returned to the San Diego and Arizona Railway Company, serving as resident engineer in charge of grading and pile bridge construction until April, 1911. From May, 1911, to June, 1914, he was assistant engineer and, from July, 1914, to April, 1917, division engineer, in charge of both location and construction through mountainous country. In April, 1917, he entered the service of the Alaska Engineering Commission at Anchorage, Alaska, as locating engineer. He was later transferred to Nenana, Alaska, as assistant to the engineer in charge of construction and operation and remained until February, 1920.

In May, 1920, Mr. Ward began a long period of service with the Division of Highways of California. He was employed in District II, with headquarters in Dunsmuir, Calif., and later in Redding, Calif., as locating engineer, superintendent of day labor construction, and resident engineer. At the time of his death Mr. Ward was resident engineer on a 33-mile mineral-access highway in the Klamath River area. He had many important assignments during his long service with the Division of Highways.

In 1922 Mr. Ward was married to Mrs. Sarah Hill of Redding. There were no children, and he was left a widower in 1939. He is survived by two brothers, R. Ernest Ward and Beverly T. Ward.

---

[1] Memoir prepared by F. W. Haselwood, M. Am. Soc. C. E., and George A. Tilton, Jr., Assoc. M. Am. Soc. C. E.

Mr. Ward was a member of the Redding Chapter of the B.P.O.E. He became a subscribing member of the Sacramento Section of the Society in 1938.

Mr. Ward was elected an Associate Member of the American Society of Civil Engineers on May 15, 1917.

TIMOTHY SILAS WILLIAMS, Assoc. M. Am. Soc. C. E.[1]

Died May 12, 1944

Timothy Silas Williams was born at Brooklyn, N. Y., on August 28, 1883, the son of Sanford H. Williams and Eliza Rebecca (Wiley) Williams. He was graduated from Pratt Institute in Brooklyn with the degree of Mechanical Engineer in 1902, received the degrees of Naval Architect and Marine Engineer from Webb Academy in New York, N. Y., in 1906, and the degree of Civil Engineer from Brooklyn Polytechnic Institute in 1910.

From June, 1906, to October, 1907, Timothy Williams was with the engineer corps on the Brighton Beach Improvement and on surveys, track layouts, and construction for the Brooklyn Rapid Transit System, as rodman, transitman, and later in charge of party. This work gave him the practical experience of the surveyor, which, together with his technical engineering training, equipped him well for his chosen field of designing engineer.

From 1908 to 1910, Mr. Williams served as civil engineering instructor at Cooper Union in New York City.

In 1910 Mr. Williams entered the employ of Westinghouse, Church, Kerr and Company, of New York City, as a structural designer. From 1912 to 1914, he was a structural steel and concrete designer at the Montreal (Canada) office of the company. Upon his return to the New York office, he served again as a structural designer until May, 1916, when he became assistant to the concrete engineer in charge of concrete and foundation design. During this ten-year period, Mr. Williams was engaged in the design of various types of steel, timber, and concrete construction—power houses, bank buildings, steel bridges and viaducts, transmission lines, coal and ore bins, crane runways, and flat slab construction.

From 1920 to 1924, Mr. Williams was employed by several engineering organizations, including The Foundation Company, Walter Kidde Company, Meinike and Frank, and the Standard Oil Company—all of New York City. During this time he supervised the design and preparation of construction drawings for industrial buildings, apartment houses, foundations, bulkheads, and piers.

In 1924 Mr. Williams joined Thomas E. Murray and Company, of New York City, as concrete engineer in responsible charge of the design of heavy power plant concrete foundation and water front construction. This experience included the use of timber, concrete, and tubular steel piling; the design of open cofferdams sealed by tremie concrete; and the construction of timber decks with concrete retaining walls, for such outstanding projects as the East River Station of the New York Edison Company and the Hell Gate Station of the United Electric Light and Power Company. Large intake flume construction below the water level designed for the support of heavy power house building and equipment foundations and bulkheads of timber and concrete with provision for intakes and screens of considerable extent made this four-year period a valuable and interesting one. For the Thomas E. Murray Company Mr. Williams wrote specifications for concrete construction, inspected sites before designing, and had frequent conferences with contractors on construction methods.

---

[1] Memoir prepared by Herbert J. Raff, Chemical Constr. Corp., New York, N. Y.

He worked for the United Engineers and Constructors of Philadelphia, Pa., from 1928 to 1931, on the preparation of estimates and plans for the West Philadelphia improvement work of the Pennsylvania Railroad Company. He was in charge of the estimating and of the complete working drawings for the $3,000,000 Railway Express Agency Building, with trackage and platform space of about 7½ acres. From 1933 to 1938, Mr. Williams had a number of professional engineering assignments with such companies as Phelps Dodge Copper Products Corporation, Wigton Abbott Company, The Texas Company, and Chemical Construction Corporation—all of New York City. He was employed as assistant structural engineer by The New York World's Fair Corporation, designing various structures and approving designs submitted by outside engineers from 1938 to 1939.

In October, 1939, Mr. Williams returned to the employ of Chemical Construction Corporation as concrete engineer and remained until his death. He was in responsible charge of design and the preparation of plans for all concrete construction and foundation work. Among the projects built from his designs were chemical plants, in the United States and abroad; the Jayhawk, Ozark, and Cactus ordnance plants for the War Department; and a number of projects sponsored by the Defense Plant Corporation.

Mr. Williams was a man of fine character, a capable structural engineer, and a good organizer and supervisor of the work of others.

On February 21, 1931, he was married to Dorothy E. Hall in Melrose, Mass. He is survived by his widow; one daughter, Elizabeth-Jeannette; and a brother, William Shaw.

Mr. Williams enjoyed music, tennis, and boating. He was an independent Republican and a Methodist. He was a licensed Professional Engineer in the states of New York and New Jersey.

Mr. Williams was elected an Associate Member of the American Society of Civil Engineers on June 16, 1919.

MERTON HORATIO WILLIS, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 7, 1943

Merton Horatio Willis was born in Burr Oak, Iowa, on August 26, 1880, the eldest of seven children of Davis Burr and Ida (Starr) Willis. His forebears were some of the earliest settlers in New England. Several years after his birth the family moved to Colorado where he spent his boyhood and young manhood.

Other than grade school, Mr. Willis had no formal education. As a boy, he was employed by a surveying party, and the chief of party encouraged him to study engineering. He began studying at night after his work for the day was finished. In this fashion he kept up his studying until at last he finished the course, continuing his active work in engineering in the meantime.

Mr Willis obtained his early engineering training with the engineering departments of the Denver, Northwestern and Pacific Railway (Moffat Road), and the Cananea, Rio Yaqui and Pacific Railway (subsidiary of Southern Pacific Company), and with contractors on railway construction work in Colorado, California, and Arizona.

After serving a three-year apprenticeship on railroad work, he commenced his engineering career in Mexico where he was destined to live and practice his profession for the next twenty years.

From 1907 to 1912, Mr. Willis was engaged chiefly in pioneer railway location and construction work in the states of Sinaloa and Jalisco, in western Mexico. Since development and operation of the many mines in these states also attracted his interest, he gradually shifted his activities from railroad engineering to mining.

In 1912 Mr. Willis was employed by the Huasteca Petroleum Company of Tampico, Mexico. One of his first and most important single tasks was the construction and initial operation of the company's first oil refinery in Mexico, followed by construction of a topping plant for the company at Desterhan, La.

On his return to Mexico in 1917 Mr. Willis was made assistant chief engineer of the Huasteca Petroleum Company and in that capacity was in immediate charge of the extensive and varied construction work required in the development of a large oil field. In addition to his interest in refinery operation, he devoted much time to the pipe line transporting oil from the company's Ebano oil field to the loading docks at Tampico. The highly viscous Mexican crude oil required an elaborate series of pumping and heating plants to handle it.

In 1927 activity in the oil fields had been brought almost to a standstill by the increasingly restrictive policies of the Mexican government. The Standard Oil Company of Indiana, which had bought out Huasteca Petroleum several years previously, in late 1927 transferred Mr. Willis to their Lake Maracaibo field in Venezuela.

---

[1] Memoir prepared by Merton Joseph Willis, Jun. Am. Soc. C. E.

After serving for a year as chief engineer, he resigned to enter contracting in the Lake Maracaibo area and on the island of Aruba, Dutch West Indies.

Mr. Willis suffered from chronic malaria for most of his twenty-five years in the tropics, and by 1932 he was in such bad health that he was told to remain for several years in a cold climate to bring the malaria under control. From 1932 to 1936 he lived first in Idaho and later in California in virtual retirement.

From 1936 until his death he was engaged in surveying and general engineering work in the vicinity of Walnut Creek, Calif.

Mr. Willis was well known in Mexican and Venezuelan oil circles as a man of integrity and outstanding practical engineering ability.

He was a member of the Knights Templar in the Masonic Order (Tampico).

On October 7, 1922, he was married in Tampico to Mary Clyde Melton. He is survived by his widow; a son, the writer; three brothers, Lawrence, Leslie I., and Burton D., Colonel in the U. S. Army; and two sisters, Una (Mrs. H. P. O'Reilly) and Clara (Mrs. E. E. Siegley).

Mr. Willis was elected an Associate Member of the American Society of Civil Engineers on January 14, 1918.

HAROLD AARON WOOD, Assoc. M. Am. Soc. C. E.[1]

Died July 17, 1944

Harold Aaron "Pete" Wood, the son of Samuel Emmor and Anne (Scott) Wood, was born in Gallup, N. Mex., on May 12, 1904.

After graduation from high school, he attended the University of New Mexico in Albuquerque for three years. He was employed by his father's engineering firm, the S. E. Wood Engineering Company of Gallup, from 1920 to 1925. In May, 1927, Mr. Wood accepted a position with the J. G. White Engineering Corporation in Panama, as instrumentman on the location and construction of railroads, and remained there until February, 1928. The following year he returned to the United States, and, after spending a year working with his father's engineering firm in Gallup, he returned to the University of New Mexico, being graduated in June, 1932, with the degree of Bachelor of Science in Civil Engineering.

For two years following his graduation, Mr. Wood was employed by the New Mexico State Highway Department, and, from February, 1934, until December, 1934, he served as surveyor for the United States Indian Irrigation Service, Department of the Interior, in Albuquerque. During 1935 Mr. Wood spent three months as project supervisor of a malaria-control project for the

---

[1] Memoir prepared by a Committee of the New Mexico Section consisting of Burton L. Smith and John H. Bliss, Assoc. Members, Am. Soc. C. E., and Berkeley Johnson, M. Am. Soc. C. E.

New Mexico State Health Department; four months as draftsman and designer on irrigation structures for the United States Indian Irrigation Service; and three months as instrumentman for W. R. Holloway, consulting engineer of Tulsa, Okla., on the investigation of a two-million-dollar domestic water supply for the City of Albuquerque.

In October, 1935, Mr. Wood returned to the employ of the United States Indian Irrigation Service in Albuquerque as junior engineer, being promoted to assistant civil engineer in July, 1939.

When the United States entered World War II, he offered his services to his country and was commissioned a Lieutenant (jg) in the United States Navy in May, 1942. He spent a year on duty in the South Pacific, and in March, 1943, was promoted to Lieutenant, stationed at Port Chicago, Calif. On July 17, 1944, he was reported missing in the Port Chicago explosion. Funeral services were conducted in Albuquerque on August 5, 1944.

Pete, as he was known to the engineers of New Mexico, and to his many business and personal acquaintances, was Secretary-Treasurer of the New Mexico Section of the Society from December, 1935, to December, 1936, and Second Vice-President from January, 1942, until he entered the Navy. To these positions he gave his usual untiring and enthusiastic effort. Work and service were enjoyable to Pete, as all those who had the privilege to be associated with him can testify. He was a registered professional engineer in New Mexico, a member of the New Mexico Society of Engineers, a Mason, and a member of Kappa Alpha fraternity (southern section).

In November, 1934, he was married to Doris Whitney of Salisbury, Vt. In addition to his widow, he is survived by a son, Samuel W., and his mother.

Lieutenant Wood was elected a Junior of the American Society of Civil Engineers on November 28, 1932, and an Associate Member on May 17, 1937.

DEANE FRANCIS BIXBY, Jun. Am. Soc. C. E.[1]

Died December 4, 1944

Deane Francis Bixby, the son of Neil F. Bixby and Bertha (Hoffman) Bixby, was born in Portland, Ore., on January 29, 1921. His parents both were born in Blue Earth County, Minnesota. They were married in Portland, where Mr. Bixby has been continuously employed with the United States Army Engineers since March 30, 1919.

Mr. Bixby received his early schooling in Parkrose grade and high schools. He attended Multnomah College in Portland for two years and then went to Oregon State College at Corvallis from which he was graduated with honors and the degree of Bachelor of Science in Civil Engineering in 1942. During his senior year at Oregon State College he was honored by election to Tau Beta Pi fraternity.

---

[1] Memoir prepared by R. E. Hickson, M. Am. Soc. C. E.

On June 4, 1942, three days after his graduation, Mr. Bixby enlisted in the United States Army and was assigned to the 826th Engineer Battalion (Aviation), at Fort George Wright in Spokane, Wash. In August, 1942, he was sent to England as a Corporal in this battalion and was engaged in the construction of airfields for the British. Almost a year later he was ordered to Officer Candidate School, at Fort Belvoir, Va., from which he was graduated as a Second Lieutenant, Corps of Engineers, on December 1, 1943. He remained at Fort Belvoir, receiving further training until he was again ordered to England in August, 1944. A month later he crossed the English Channel to France, assigned to Company C, Eighth Engineer Combat Battalion. Lieutenant Bixby fought and performed the arduous duties demanded of an officer in the combat engineers during the historic campaign which drove the Germans out of France. He was seriously wounded in action in Germany on November 27, and died on December 4, 1944. He is buried "somewhere in Belgium."

Lieutenant Bixby was an engineer of promise; he was true to his many friends who sincerely miss him. He had hopes and aspirations for success and service in his chosen profession, and above all he had a fervent desire to serve his country.

In addition to his parents, Lieutenant Bixby is survived by three sisters, Shirley, Patricia, and Evelyn (Mrs. H. R. Strong).

Lieutenant Bixby was elected a Junior of the American Society of Civil Engineers on October 19, 1942.

JOHN EDWARD BUSSELL, Jun. Am. Soc. C. E.[1]

DIED JUNE 6, 1944

John Edward Bussell, the son of Edward E. and Lora Mabel (Miles) Bussell, was born in Coffeyville, Kans., on November 17, 1919. He was graduated from St. Joseph Junior College at St. Joseph, Mo., in 1938 and from the University of California at Berkeley in 1941.

From May to November, 1941, Mr. Bussell was employed as junior engineer by East Bay Municipal Utility District of Oakland, Calif. He then spent several months as student engineer of the Special Engineer Division on preliminary work for the Third Locks of the Panama Canal.

Returning to the United States, he enlisted in the U. S. Naval Reserve (U.S.N.R.). Mr. Bussell was appointed Midshipman in March, 1943, and was sent to Naval Reserve School in New York, N. Y. In June, 1943, he was appointed Assistant Civil Engineer with the rank of Ensign, CEC–V(S), U. S. N. R., and, after several months of training with an Amphibious Demolition Unit, was sent overseas in January, 1944.

---

[1] Memoir prepared by a Committee of the Kansas City Section consisting of Chester A. Smith, M. Am. Soc. C. E., and E. A. Blanpied, Assoc. M. Am. Soc. C. E.

On June 6, 1944, he was killed on Omaha Beach in Normandy, France, where his unit of Force O formed part of the first wave of the attack and met devastating artillery, machine gun, and sniper fire but blasted five gaps for the assault forces and removed German traps from 85% of the Omaha Beach area. The unit received a citation for the action but lost over 50% of its men in killed and wounded.

He was a member of the Chi Epsilon, civil engineering professional honor society.

Ensign Bussell was elected a Junior of the American Society of Civil Engineers on October 9, 1941.

HARRY HAMILTON HOLTON, Jun. Am. Soc. C. E.[1]

Died July 10, 1944

Harry Hamilton Holton was born in Tupelo, Miss., on September 12, 1920, the son of John Calvin and Ruth (Crook) Holton. After graduation from the Jackson (Miss.) High School in 1937, he entered Mississippi State College, at State College, from which he was graduated in June, 1941. He majored in civil engineering, and was a member of the Mississippi State College Student Chapter of the Society. He was very popular with students and faculty members, and was quite active in campus affairs, serving as an officer in his social fraternity, Kappa Sigma, for three years. He also made many friends when he traveled with his father on trips while the latter was Commissioner of Agriculture for the State of Mississippi.

As a result of his training in the Reserve Officers' Training Corps at Mississippi State College, Mr. Holton was eligible for a commission as a Second Lieutenant in the U. S. Army Reserve Corps upon graduation; but this was not granted until February, 1942, when he was twenty-one years old. From June, 1941, to January, 1942, he was with the Tennessee Valley Authority, in charge of a mapping and surveying crew. In the meantime he transferred from the Coast Artillery to the Air Corps, and was called to active duty as an Administrative Officer, reporting to Patterson Field, Ohio, in March, 1942. Imbued with the spirit of rendering the greatest possible service, Lieutenant Holton applied for pilot training, reported to Maxwell Field, Alabama, in June, 1942, and received his "wings" at Spence Field, Moultrie, Ga., in January, 1943.

Although he was trained for fighter plane duty, he was first assigned to the Ferrying Command, flying planes and supplies from the Northwest, particularly Billings, Mont., and Minneapolis, Minn., to Nome and Fairbanks, Alaska. He was sent overseas in June, 1943. In July, 1943, he was assigned to the Air Transport Command, flying over the "'Hump" (Himalaya Mountains) from India to China—probably the most hazardous duty in the entire war theater. He had this assignment for a little more than a year, with the exception of about two months when, because of his civil engineering training, he was called on to serve as a technical adviser on the selection of airport sites and on the inspection of established fields in India. Lieutenant Holton received a Presidential Citation for "meritorious service" in the spring of 1944, and was promoted to First Lieutenant. It was rumored that a captaincy was to follow. He was killed in an airplane crash at Kunming, China.

---

[1] Memoir prepared by Robert E. Bowlus. Arlington, Va.

On May 1, 1943, Lieutenant Holton was married to Jean Morris, daughter of Mr. and Mrs. Lloyd Morris of Yazoo City, Miss. Mrs. Holton was then a junior at Vanderbilt University in Nashville, Tenn., and, in the fall of 1943, following Lieutenant Holton's assignment overseas, she entered Millsaps College, in Jackson, where she completed her college work in February, 1944. Lieutenant Holton's death came as a very great shock to the Holton and Morris families, as he was expecting to return to the United States in the fall of 1944, having already served for nearly thirteen months overseas. He is survived by his parents; his widow; and a sister, Dorothy (Mrs. A. B. Kelly).

Lieutenant Holton was elected a Junior of the American Society of Civil Engineers on October 9, 1941.

EUGENE CLARE MILLER, Jun. Am. Soc. C. E.[1]

Died February 10, 1944

Eugene Clare Miller, the son of Ernest and Clara Blanche (Snyder) Miller, was born in Glendora, Calif., on July 6, 1913. Mr. Miller spent his early life in Glendora and Whittier, Calif. Upon completion of high school, he entered the California Institute of Technology at Pasadena. In June, 1935, he was graduated with the degree of Bachelor of Science in Civil Engineering and immediately started to work for the United States Forest Service in Glendora as a junior engineer. Shortly thereafter, he became a concrete inspector for A. C. Martin, an architect of Los Angeles, Calif.

During 1936, he was timekeeper, draftsman, and engineer for both the Jahn and Bressi Construction Company and H. C. Nelson, structural engineer, in Los Angeles. He later became a bridge steel inspector for the United States Army Engineers. In December, 1936, he started work as a draftsman for Consolidated Steel Corporation, Ltd., in Los Angeles. For the next few years he worked as a detailer (structural and reinforcement) and as a labor and material estimator. At the beginning of 1942 he was appointed chief estimator for Consolidated Steel Corporation, Ltd.

In this capacity, with his background of education and experience, Mr. Miller was an invaluable man to the company, as his duties required a combination of capability, personality, experience, and tact. Mr. Miller had all these qualities, as was evidenced by his many friendships—both business and social. His services were invaluable for he was careful and accurate in his work, and possessed driving energy and leadership. In spite of the tremendous effort and long hours required of him, he was still able to find time to enjoy sports of all kinds, being a particular devotee of bowling and fishing, especially deep-sea fishing.

---

[1] Memoir prepared by Edward R. Bosley, Jr., Director of Public Relations, Consolidated Steel Corp., Ltd., Los Angeles, Calif.

During February, 1944, Mr. Miller was on his way to Washington, D. C., on important war business, when the ill-fated plane on which he was a passenger crashed into the Mississippi River, and all aboard were lost.

On September 24, 1936, in Glendora, he was married to Grace Wills. He is survived by his widow; his young son, Ernie, aged four; his parents, Mr. and Mrs. Ernest Miller; a brother, Victor A., Ensign, United States Navy; and a sister, Betty Louise (Mrs. Robert McPhetridge).

Mr. Miller was elected a Junior of the American Society of Civil Engineers on December 9, 1935.

HARRY ALFRED PARR, Jun. Am. Soc. C. E.[1]

DIED NOVEMBER 27, 1944

Harry Alfred Parr, the son of Harry and Hetty (Feist) Parr, was born in Roslindale, Mass., on March 25, 1917. He was graduated from the University of New Hampshire, at Durham, in 1941 with the degree of Bachelor of Science in Civil Engineering.

After graduation from college, Mr. Parr entered government service in the United States Engineering Department, remaining until he was commissioned a Second Lieutenant in the Corps of Engineers, United States Army.

Lieutenant Parr received his basic training at Fort Belvoir, Va. He then went to Camp Gruber, Okla., where he was promoted to First Lieutenant. In January, 1944, he went overseas, and was killed in action on November 27, 1944.

His commanding officer, Lt.-Col. Philip C. Satterthwaite, wrote of Lieutenant Parr:

> "First Lt. Harry A. Parr * * * was a fine gentleman and an excellent officer. He was admired and respected by everyone for his ability and pleasant personality. He fully deserved a promotion to Captain which I had, as yet, been unable to give him * * *."

Harry A. Parr was a very modest young man, sensible, and courageous. He was persevering in anything he undertook to do. While a student at the university, he was a member of the Reserve Officers' Training Corps. Both in high school and at college, he was a member of the football teams.

---

[1] Memoir prepared by Mrs. H. A. Parr, Hampton, N. H.

While at the university, Lieutenant Parr belonged to the local Student Chapter of the Society, and was president during his senior year. When he was graduated from Hampton High School, he received a gold honor medal.

In 1942 he was married to Evelyn Ruth Brown of Camden, Me. He is survived by his widow; a son, Randall Alfred Parr, whom he had never seen; his parents; two brothers, Richard A. and Robert G. Parr; and two sisters, Doris I. and Lorraine E. Parr.

Lieutenant Parr was elected a Junior of the American Society of Civil Engineers on October 9, 1941.

MILTON HARRY SCHOERPNER, Jun. Am. Soc. C. E.[1]

Died September 12, 1944

Milton Harry Schoerpner was born in the Borough of the Bronx, New York, N. Y., on July 24, 1917. Both his father, Rudolph Schoerpner, and his mother, Olga (Kraus) Schoerpner, were born in what was later Czechoslovakia; both came separately to the United States when quite young and were married in this country. In spite of the difficulties and handicaps which confront recent immigrants, Rudolph Schoerpner was able eventually to go into business for himself and to operate his own restaurant until his death in 1930.

Mr. Schoerpner obtained both his secondary and college education in New York City. After graduation from Stuyvesant High School in 1934, he entered New York University. For the following eight years, he attended evening classes, working during the day to earn a livelihood and at the same time to finance his education. He was employed as stock clerk in the firm of G. Schirmer in New York City, and held clerical positions in other New York City and Long Island firms, among them the A. C. Horn Company, where he became assistant office manager. Although the positions he held involved full-time employment with varying degrees of responsibility and although he was required to meet the same high scholastic standards in his evening classes as students in the regular sessions, Mr. Schoerpner, in his determination to enter the professional world, took full advantage of every opportunity to realize his ambition. By combining industry and native ability, he carried on his intensive double program of work and scholastic endeavor without interruption until July, 1942, when he was graduated from New York University with the degree of Bachelor of Civil Engineering.

The attainment of this engineering degree in spite of such great handicaps is ample evidence of Mr. Schoerpner's ambition and of his determination to achieve his goal. If success consists in the attainment of one's ideals, he was successful before his career as an engineer actually began.

---

[1] Memoir prepared by Arthur W. Harrington, M. Am. Soc. C. E.

Immediately after graduation, Mr. Schoerpner received an appointment as junior hydraulic engineer and was assigned to the office of the United States Geological Survey, Water Resources Branch, in Albany, N. Y. He remained with this organization until his induction into the United States Army. His investigational work with the Geological Survey was of excellent quality, and he displayed more than sufficient ability to assure his engineering future.

Mr. Schoerpner was inducted into the Army on September 2, 1943, and reported for active duty at Camp Upton, Long Island, N. Y., on September 23, 1943. About two weeks later, he was sent to Camp Claiborne, La., for basic training, after which he was transferred to the Granite City Engineering Depot in Granite City, Ill., for special training. Early in May, 1944, he left with his outfit for England and from there he was shipped to France, landing about August 15, 1944. Comprehensive details with respect to his Army work, which concerned supplies to embattled areas, cannot be released, but it is known that his group was engaged in experimental work to facilitate the movement and repair of heavy equipment.

On September 12, 1944, Corporal Schoerpner was killed near Longny, France, as a result of a motor transport accident. He is buried in the American Military Cemetery at St. Corneille, France, where, on September 16, 1944, officers and men of his company paid him full military honors. In the Army, he was highly regarded by both superiors and subordinates, and, for efficiency and fidelity in service, Corporal Schoerpner was awarded the Good Conduct Medal posthumously.

Hampered both by lack of time and of resources, Mr. Schoerpner had made only a fair start on such hobbies as a collection of electric trains (which included, and was built up from, the first set which had been given to him as a boy) and a collection of coins. His particular enthusiasm was photography.

On November 15, 1942, in New York City, he was married to Madeline Beer. He is survived by his widow.

Mr. Schoerpner belonged to the Albany Society of Engineers and to the American Geophysical Union. While attending New York University, he was an active member of the Student Chapter (Evening Section) of the Society, and served as Secretary for one year.

Mr. Schoerpner was elected a Junior of the American Society of Civil Engineers on November 9, 1942.

HOWARD EARLE SHAW, JR., Jun. Am. Soc. C. E.[1]

DIED OCTOBER 2, 1943

Howard Earle Shaw, Jr., the son of Howard Earle and Kate (Worley) Shaw, was born on December 7, 1913, in Andover, Mass.

---

[1] Memoir prepared by W. S. Evans, M. Am. Soc. C. E.

He received his preparatory education at Deering High School and attended the University of Maine, at Orono, being graduated with the degree of Bachelor of Science in Civil Engineering in June, 1937. The next year he attended the Graduate School of Sanitary Engineering at Harvard University, in Cambridge, Mass., and received the degree of Master of Science.

In September, 1938, Mr. Shaw was employed by the Portland (Me.) Water District as research engineer on the development of algae strainers. A year later he was employed as junior engineer inspector, Public Works Administration, on office and field work for the inspection of a submarine water main at Bath, Me. In the fall of 1939 he was construction engineer for Sanders Engineering Company on hydroelectric work at Hiram Falls, Me.

During college, Mr. Shaw was active in military affairs, being elected to Scabbard and Blade. He was commissioned a Second Lieutenant in the Reserve Officers Corps upon graduation. While employed as safety engineer by the Liberty Mutual Insurance Company of Philadelphia, Pa., he was called to active duty on May 5, 1941, as a First Lieutenant, assigned to 8th Infantry, Fort Benning, Ga., and later to 385th Infantry, 76th Division, and was promoted to rank of Captain on August 11, 1942. He attended the Infantry School in Fort Benning, and the Command and General Staff School, in Fort Leavenworth, Kans., then rejoined the 385th Infantry at Fort George G. Meade, Md., on April 10, 1943. He left the United States on July 15, 1943, for Casablanca, Morocco. He was in charge of water and sanitation at a large prisoner-of-war camp somewhere in the North Africa area. Following this he was transferred to Sicily, Italy, on September 15, 1943, reporting to 3d Division Headquarters and soon was assigned to command of Company M, 30th Infantry, operating somewhere in Italy. At about nine o'clock on the morning of October 2, 1943, while making a reconnaissance for suitable position to employ his heavy machine guns and mortars, he was instantly killed by a sudden burst of fire from a German machine pistol. Captain Shaw was buried in an American Military Cemetery in Italy on October 4, 1943.

Captain Shaw possessed a genial and winning personality. Cheerful and optimistic by nature, daily association with him in his work and elsewhere was most congenial and pleasant. Well trained, capable, loyal, and conscientious in his work, his brief career as a civil engineer will always reflect honor upon his name and upon the profession to which he belonged.

On September 1, 1940, in Andover, Captain Shaw was married to Eleanor Elizabeth Manning. Besides his parents, he is survived by his widow; a daughter, Susan Margaret, born on November 14, 1942; and a sister, Katharine (First Lieutenant in the Women's Army Corps).

Captain Shaw was elected a Junior of the American Society of Civil Engineers on April 10, 1940.

FREDERICK QUAAS TEICHERT, Jun. Am. Soc. C. E.[1]

Died May 12, 1944

Frederick Quaas Teichert was born in Sacramento, Calif., on August 7, 1915, the son of Adolph Teichert, Jr., and Augusta (Quaas) Teichert. He attended the public schools of that city and was valedictorian of his class upon his graduation from the Sacramento High School.

After majoring in civil engineering for two years at the Sacramento Junior College, he continued his engineering education at the University of California in Berkeley, receiving the degree of Bachelor of Science in Civil Engineering in 1936. He was a member of Tau Beta Pi, engineering honor society, and served as president of the university chapter. In addition, he was affiliated with the Psi Upsilon fraternity, was president of the Student Chapter of the Society, and a member of the Student Engineering Council.

After graduation, Mr. Teichert joined his father as a member of the old and established contracting firm of A. Teichert and Son, Inc. He held various positions in the firm before advancing to that of vice-president. During the years he was in business with his father, Mr. Teichert worked on various airport, highway, and levee construction projects. Two of his outstanding accomplishments were coordinating the construction of the Sierra Ordnance Depot, a $12,000,000 project in Lassen County, California, which was completed in five months during 1942, and the construction of the Debris Dam on the North Fork of the American River (California) for the U. S. Army Engineers. He was a director of the Northern California Chapter of Associated General Contractors of America.

Mr. Teichert possessed initiative, leadership, and originality to an unusual degree, and displayed exceptional capacity for success in the engineering profession. His superior executive ability, which was far beyond his years, qualified him to execute important engineering projects.

Popular and likable, Mr. Teichert was a young man of high character, integrity, and ideals, and his passing is a great loss to the community, as well as to his many friends and relatives. He is survived by his widow, Norma Watrous Teichert, to whom he was married on January 20, 1940, in Sacramento; his father, Adolph Teichert, Jr.; a sister, Nancy Teichert; and two brothers, Adolph H. Teichert and Capt. Henry Teichert of the U. S. Army Air Corps.

Mr. Teichert was presented the Junior Prize for the year 1936 by the Sacramento Section of the Society. He was selected as recipient for this award on the basis of scholarship, his creditable record of activities in the Student Chapter of the Society, and his capacity for success in his chosen profession.

Mr. Teichert was elected a Junior of the American Society of Civil Engineers on December 14, 1936.

---

[1] Memoir prepared by O. Haven Hart and Roy J. Sykes, Assoc. Members, Am. Soc. C. E.

ALFRED EPHRAIM KORNFELD, Affiliate Am. Soc. C. E.[1]

Died April 8, 1944

One of the small group of able men who developed American engineering journalism in its early days passed away with the death of Alfred Ephraim Kornfeld in New York, N. Y., on April 8, 1944. His share in the upbuilding of *Engineering News,* as its business manager, may justly be ranked as a contribution to the development of the civil engineering profession in the United States. The editorial leadership of Arthur M. Wellington,[2] M. Am. Soc. C. E., and his technical collaborators found a necessary supplement in the business genius of Mr. Kornfeld in association with that of George H. Frost,[3] Assoc. M. Am. Soc. C. E. They gave the enterprise vitality and stability.

Alfred Ephraim Kornfeld, the son of Karl and Julia (Grögor) Kornfeld, was a native New Yorker, born in the metropolis on October 24, 1869. He was educated in the public schools and the College of the City of New York. His business abilities revealed themselves at an early age and he was employed in the commercial and advertising departments of technical papers while still in his teens. This work inspired him with the initiative and confidence to propose to Mr. Frost, the founder of *Engineering News,* that he be entrusted with the advertising representation of the paper. Mr. Frost's insight into human nature led him to agree to the proposal, and Mr. Kornfeld's immediate success under discouraging circumstances (the dark days of the 1893 economic depression) justified the wisdom of the decision.

The quick understanding, clear business sense, integrity, and human qualities responsible for his success soon carried Mr. Kornfeld farther—to the business managership of the publication and participation in its ownership. He continued to be a leading spirit in the direction of *Engineering News* until 1912, when Mr. Frost's retirement led to its transfer to the Hill Publishing Company (later merged with the McGraw Publishing Company to form the McGraw-Hill Publishing Company). Mr. Kornfeld turned over his work to younger hands, although he maintained his active interest in *Engineering News* and its successor, *Engineering News-Record,* up to the time of his death.

In his later years, Mr. Kornfeld's interest was centered in philanthropic and civic work, and even during occasional reentry into business ventures these activities continued to hold first place. He gave help to both individuals and groups, and had the satisfaction of making many people happier.

On June 21, 1891, Mr. Kornfeld was married to Hennie Eisenberg, of New York City, who, with a daughter, Muriel (Mrs. Franklin Hollander), survives him.

---

[1] Memoir prepared by F. E. Schmitt, M. Am. Soc. C. E.

[2] For memoir, see *Proceedings,* Am. Soc. C. E., Vol. XXI (1895), p. 199.

[3] For memoir, see *Transactions,* Am. Soc. C. E., Vol. LXXXI (December, 1917), p. 1827.

His technical and scientific memberships included the American Society of Mechanical Engineers, the American Association for the Advancement of Science, the Society of American Military Engineers, and the American Institute of the City of New York.

Mr. Kornfeld was elected an Affiliate of the American Society of Civil Engineers on October 7, 1908.

Military airfields. 743.

JERVIS, WILLIAM H.
Military airfields. 797.

JOACHIMSON, MARTIN
Memoir of. 1737.

JOHNSON, FRANK MINITREE
Memoir of. 1738.

JOHNSON, LLOYD M.
Use of sewage sludge. 254.

JOHNSTONE, DON
Storage. 1474.

JONES, JONATHAN
"Rainbow Arch Bridge Over Niagara Gorge (Symposium): Fabrication and Erection Controls." 50.

JUDD, FRANK RHYMAL
Memoir of. 1741.

KAHN, JULIUS
Memoir of. 1742.

KALINSKE, A. A.
Velocity distribution. 645.

KEEFER, C. E.
"Concentration of Sewage Sludge (Symposium): Back River Sewage Works, Baltimore, Md." 1562.

KEENE, PHILIP
Highway engineering. 306.

KELLOGG, F. H.
Highway engineering. 300.

KENNEDY, ROBERT E.
Storage. 1459.

KING, WINFIELD SCOTT
Memoir of. 1748.

KINNISON, H. B.
"Flood Formulas Based on Drainage Basin Characteristics." 849.

KIRKBRIDE, WALTER HAROLD
Memoir of. 1748.

KOMORA, ANDREW M.
"Erection of Hydraulic Turbines and Generators." 581.

KORNFELD, ALFRED EPHRAIM
Memoir of. 1921.

KREISS, ROBERT F.
Lock manifold experiments. 1389.

KRYNINE, D. P.
Cellular cofferdams. 1175.
Highway engineering. 328.
"Pressure on the Lining of Circular Tunnels in Plastic Soils." 1048.

KUMMER, FREDERIC ARNOLD
Memoir of. 1751.

LANSFORD, W. M.
Lock manifold experiments. 1388.
Translatory waves. 1227.

LAUTZ, MARTIN W.
Cellular cofferdams. 1165.

LEGGET, ROBERT F.
Circular cofferdams. 1173.
Highway engineering. 332.

LEWIS, EDWARD ROWLAND
Memoir of. 1755.

LEYPOLDT, HARRY
Canal surges. 356.

LINSLEY, RAY K., JR.
Storage. 1452.

LOGAN, SAMUEL T.
"Shear and Bond Stresses in Reinforced Concrete." 599.

LOHMANN, FREDERICK CHARLES
Memoir of. 1757.

LOOK, MOSES JEROME
Memoir of. 1758.

MACK, EDWARD RESOLVED
Memoir of. 1893.

MACKINTOSH, CHARLES
Rainbow Arch Bridge. 121.

McCONAUGHY, D. C.
Canal sections. 435.

McCOY, BYRON O.
Flood formulas. 891.

McELDOWNEY, ROBERT, JR.
"Rainbow Arch Bridge Over Niagara Gorge (Symposium): Moments in Flexible Two-Hinged Arches." 35.

McFADDEN, JAMES ALEXANDER
Memoir of. 1894.

McGEE, ARTHUR B.
Amplified slope deflection. 1412.
Analysis by superposition. 1522.

McLAUGHLIN, C. P.
"Dewatering, Incineration, and Use of Sewage Sludge (Symposium): Experience of Chicago, Ill., in the Preparation of Fertilizer." 218.

McMANUS, JOHN HERBERT
Memoir of. 1760.

McNAUGHER, DAVID WHITE
Memoir of. 1762.

McNOWN, JOHN S.
Lock manifold experiments. 1378.
Velocity distribution. 651.

McQUIRE, D. D.
Military airfields. 776.

MARSHALL, H. E.
Highway engineering. 309.

MEAD, LAWRENCE M., JR.
"Rainbow Arch Bridge Over Niagara Gorge (Symposium): Moments in Flexible Two-Hinged Arches." 35.

MENDELSOHN, ISADOR W.
Use of sewage sludge. 255.

MENSCH, L. J.
Military airfields. 831.
Rainbow Arch Bridge. 128.

MERRITT, FREDERICK S.
Analysis by superposition. 1509.
Characteristic redundants. 1291.

MEYER, OTTO H.
Storage. 1448.

MILLARD, CHARLES STERLING
Memoir of. 1763.

MILLER, EUGENE CLARE
Memoir of. 1915.

MILLER, J. S.
Cellular cofferdams. 1170.

MINIHAN, JOHN FRANCIS
Memoir of. 1895.

MITCHELL, WILLIAM JOHNSTON
Memoir of. 1897.

MONEYMAKER, BERLEN C.
Cutoff problems. 995.
Highway engineering. 302.

MOORE, EGBERT JESSUP
Memoir of. 1764.

MOORE, R. WOODWARD
Highway engineering. 320.

MOORMAN, ROBERT B. B.
"Wedge-Shaped Structural Members Under Direct Stress and Bending." 1581.

MORGAN, FRANK I.
Erection of turbines. 594.

MULLIS, IRA B.
Military airfields. 826.

MURRAY, D. O.
Military airfields. 790.

MYRON, JOHN PATRICK
Memoir of. 1766.

NEUMAN, DAVID LEONARD
Memoir of. 1768.

NEWELL, JOSEPH PETTIS
Memoir of. 1770.

NEWMAN, JAMES B., JR.
Military airfields. 734.

NORRIS, WALTER HENRY
Memoir of. 1775.

NUBAR, YVES
"Analysis of the General Two-Dimensional Framework." 905.

OBERT, RUSSELL MELVIN
Memoir of. 1898.

OLDER, CLIFFORD
Memoir of. 1777.

ORD, M. J.
Flood formulas. 886.

ORR, DAVID KIRK
Memoir of. 1778.

ORROK, GEORGE ALEXANDER
Memoir of. 1779.

OWEN, ARTHUR EDMUND
Memoir of. 1783.

PACKSHAW, SAVILE
Cellular cofferdams. 1161.

PALEN, ARCHIBALD E.
Memoir of. 1785.

PARKER, THEODORE BISSELL
Memoir of. 1786.

PARMER, E. D.
Military airfields. 776

PARR, HARRY ALFRED
Memoir of. 1916.

PEABODY, DEAN, JR.
Shear and bond. 610.

PEARSE, LANGDON
Use of sewage sludge. 261.

PENNOYER, RAYMOND P.
Cellular cofferdams. 1124.

PICKELS, GEORGE WELLINGTON
Memoir of. 1790.

PIETRKOWSKI, J.
Lock manifold experiments. 1377.

PILL, JOHN RICHARDS GRAY
Memoir of. 1792.

PINNEY, JAMES CHARLES
Memoir of. 1794.

PITTMAN, H. V.
Military airfields. 814.

PNEUMAN, FRED ASHLEY
Memoir of. 1795.

POLIVKA, JAROSLAV
  Amplified slope deflection. 1414.
  Analysis by superposition. 1529.
  Cellular cofferdams. 1178.
  Two-dimensional framework. 940.
POSEY, C. J.
  Canal sections. 436.
  Canal surges. 358.
POST, WILLIAM SCHUYLER
  Memoir of. 1899.
POWELL, RALPH W.
  Lock manifold experiments. 1394.
PRINGLE, THOMAS B.
  Military airfields. 792.
PROCTOR, RALPH R.
  Military airfields. 799.
PURDY, CORYDON TYLER
  Memoir of. 1797.
PYLE, IRA LAWRENCE
  Memoir of. 1801.
PYLE, MILTON ALLENDER
  Memoir of. 1802.
QUICK, ALFRED MERRITT
  Memoir of. 1803.
RAISMAN, AARON ISRAEL
  Memoir of. 1806.
RAPP, WILLIAM G.
  Rainbow Arch Bridge. 139.
REA, DALE H.
  Haunched beams. 1042.
REISSNER, H.
  Aerodynamic stability. 501.
RICHARDSON, EDWARD ADAMS
  Aerodynamic stability. 476.
RICHARDSON, FREDERICK HOSEA
  Memoir of. 1807.
RICKETTS, ALLAN TOWNSHEND
  Memoir of. 1810.
ROBBINS, FRANKLIN HENRY
  Memoir of. 1811.

ROBERTS, J. F.
Erection of turbines. 595.

ROBERTSON, J. M.
Aerodynamic stability. 487.

ROUSE, HUNTER
Velocity distribution. 651.

RUDOLFS, WILLEM
"Concentration of Sewage Sludge (Symposium): Some Results in the State of New Jersey." 1565.
Use of sewage sludge. 251

RUDOLPH, WILLIAM E.
Military airfields. 751.

SALMON, JOHN McCLURE
Memoir of. 1813.

SCHMIDT, L. A., JR.
"Unusual Cutoff Problems—Dams of the Tennessee Valley Authority (Symposium): Flowing Water in Underground Channels, Hales Bar Dam, Tennessee." 965.

SCHNEIDER, G. R.
Military airfields. 818.

SCHOERPNER, MILTON HARRY
Memoir of. 1917.

SCHROEPFER, GEORGE J.
"Dewatering, Incineration, and Use of Sewage Sludge (Symposium): Possible Economies in Sludge Disposal Practice." 194.

SEAVER, GEORGE ARTHUR
Memoir of. 1814.

SEIFRIED, CHARLES FRANK
Memoir of. 1815.

SERGEV, S.
"Shear Effect on the Strength of Struts." 391.

SHANLEY, F. R.
Shear and bond. 607.

SHAW, HOWARD EARLE, JR.
Memoir of. 1918.

SHERMAN, JOHN
Haunched beams. 1041.

SHERMAN, L. K.
Storage. 1449.

SMITH, FREDERICK C.
Aerodynamic stability. 512.

SMITH, GILMAN WALTER
Memoir of. 1818.

SMITH, HOWARD EVERETT
Memoir of. 1820.

SMITH, MARION deKALB, JR.
Memoir of. 1901.

SNYDER, FRANKLIN F.
Storage. 1465.

SOUCEK, EDWARD
"Lock Manifold Experiments." 1357.
Miter gate operation. 1314.
"Surges in Panama Canal Reproduced in Model." 345.

SPARHAWK, GEORGE FRANCIS
Memoir of. 1821.

SPIKER, WILLIAM C.
Amplified slope deflection. 1411.
Analysis by superposition. 1539.

SPOFFORD, C. M.
Rainbow Arch Bridge. 127.

STANTON, THOMAS E.
Military airfields. 737.

STAPE, GEORGE PHILIP ALEXANDER
Memoir of. 1902.

STEINMAN, D. B.
"Rigidity and Aerodynamic Stability of Suspension Bridges." 439.

STEPHENS, ALLEN WHITMORE
Memoir of. 1823.

STERN, GEORGE
Rainbow Arch Bridge. 163.

STEVENS, CHARLES HENRY
Memoir of. 1824.

STEVENS, J. C.
"Private Enterprise." 1605.

STEWART, RALPH W.
"Amplified Slope Deflection." 1401.
Analysis by superposition. 1510.
Characteristic redundants. 1282.

STONE, WILLARD WILBERFORCE
Memoir of. 1831.

STRATTON, JAMES H.
"Military Airfields (Symposium): Construction and Design Problems." 670.

STREETER, VICTOR L.
"Economical Canal Cross Sections." 421.

SUMNER, MERTON ROGERS
Memoir of. 1835.

SWEENEY, JOHN CALVIN
Memoir of. 1836.

SWEET, JAMES S.
Storage. 1447.

TALBERT, CHARLES MASON
Memoir of. 1840.

TAYLOR, EDWARD H.
Velocity distribution. 646.

TEICHERT, FREDERICK QUAAS
Memoir of. 1920.

TEN EYCK, PETER GANSEVOORT
Memoir of. 1842.

TERZAGHI, KARL
Highway engineering. 324.
"Stability and Stiffness of Cellular Cofferdams." 1083.

THANHEISER, CHARLES AUGUST
Memoir of. 1903.

THOMSON, T. KENNARD
Rainbow Arch Bridge. 125.

TIMBY, ELMER K.
"Rainbow Arch Bridge Over Niagara Gorge (Symposium): Moments in Flexible Two-Hinged Arches." 35.

TRASK, FRANK ELLSWORTH
Memoir of. 1843.

TRIPP, WILLIAM A.
Miter gate operation. 1320.

TSAGARIS, DEAN P.
Cellular cofferdams. 1133.

TURNBULL, W. J.
Military airfields. 797.

TURNER, HOWARD M.
Flood formulas. 888.
Storage. 1471.

TYRRELL, HARRY EDWARD
Memoir of. 1845.

UTEGAARD, THOMAS
Memoir of. 1846.

VAN DRIEST, E. R.
Velocity distribution. 648.

VAN EENAM, NEIL
Rainbow Arch Bridge. 150.

VAN KLEECK, LeROY W.
"Dewatering, Incineration, and Use of Sewage Sludge (Symposium): Use of Sewage Sludge as Fertilizer." 208.

VELZY, C. R.
"Dewatering, Incineration, and Use of Sewage Sludge (Symposium): Developments Indicated by Experience at Buffalo, N. Y." 181.
Sludge concentration. 1579.

VINCENT, GEORGE S.
Aerodynamic stability. 512.

WADE, JEPTHA ALAN
Memoir of. 1850.

WADHAMS, JOSEPH PALMER
Memoir of. 1852.

WAITE, HENRY MATSON
Memoir of. 1631.

WALKER, ELTON DAVID
Memoir of. 1853.

WALKER, JOSEPH JEANES
Memoir of. 1905.

WALL, EDWARD EVERETT
Memoir of. 1635.

WARD, HERBERT KIRKMAN
Memoir of. 1907.

WEGGEL, HAROLD A.
Canal surges. 356.
Translatory waves. 1226.

WEIDEL, JOSEPH
Memoir of. 1855.

WEISS, CAMILLO
Amplified slope deflection. 1411.

WETZLER, WILLIAM HENRY
Memoir of. 1856.

WHEELER, WALTER H.
Wedge-shaped members. 1599.

WHITEHEAD, LINDSEY WOOD
Memoir of. 1858.

WILBUR, JOHN B.
"Characteristic Redundants Used for Analyzing Statically Indeterminate Structures." 1257.

WILBUR, WILLIAM E.
Shear and bond. 612.

WILKINSON, J. H.
"Translatory Waves in Natural Channels." 1203.

WILLIAMS, GORDON R.
Storage. 1451.

WILLIAMS, H. M.
Military airfields. 820.

WILLIAMS, TIMOTHY SILAS
Memoir of. 1908.

WILLIS, MERTON HORATIO
Memoir of. 1910.

WILLOUGHBY, JULIUS EDGAR
Memoir of. 1859.

WILSON, DAVID M.
"Analysis of Rigid Frames by Superposition." 1489.

WINTER, GEORGE
Wedge-shaped members. 1595.

WITTEN, DONALD
Memoir of. 1861.

WOOD, HAROLD AARON
Memoir of. 1911.

WOOD, LYMAN W.
Highway engineering. 306.

WOODS, K. B.
Highway engineering. 312.

YOUNG, JOSEPH HENRY
Memoir of. 1863.

ZELNICK, E. W.
"Lock Manifold Experiments." 1357.
